If we take a garden-bean, we may perceive each of these three parts with great ease; for this seed is of so large a size, that all its organs are exceedingly distinct. When we strip off the external coats of the bean, which are two, and of different degrees of thickness in different parts, we find that it easily divides into two lobes, pretty nearly of the same size and figure. Each of these lobes is called a cotyledon. The cotyledons of the bean, then, are two in number.

Near that part of the lobes which is contiguous to what is called the eye of the bean, there is a small round white body, which comes out between the two lobes. This body is called the radicle.

Attached to the radicle there is another small round body, which lies between the cotyledons, and wholly within them, so that it cannot be seen till they are separated from each other. This body is called the plumula.

The appearance and shape of these three parts differ very much in different seeds, but there is no seed which wants them. The figure and size of the seed depend chiefly upon the cotyledons. This is evidently the case with the bean, and it is so with all other seeds. The number of cotyledons is different in different seeds. Some seeds have only one cotyledon, as the seeds of wheat, oats, barley, and the whole tribe of grasses; some have three; others six, as the seeds of the garden-cress; but most seeds, like the bean, have two cotyledons.

When a seed is placed in a situation favourable to vegetation, it very soon changes its appearance. The radicle is converted into a root, and sinks into the earth; the plumula, on the other hand, rises above the earth, and becomes the trunk or stem. When these changes take place the seed is said to germinate.

nate: the process itself has been called germination. Seeds do not germinate equally and indifferently in all places and seasons. Germination, therefore, is a process which does not depend upon the seed alone: something external must also affect it.

It is a well-known fact, that seeds will not germinate without moisture; for seeds, if they are kept perfectly dry, never vegetate at all, and yet their power of vegetating is not destroyed. Water, then, is essential to germination. Too much water, however, is no less prejudicial to most seeds than none at all. The seeds of water-plants, indeed, germinate and vegetate extremely well in water; but most other seeds, if they are kept in water beyond a certain time, are rotted and destroyed altogether.

It is well known also, that seeds will not germinate, even though supplied with water, provided the temperature is below a certain degree. No seed, for instance, on which the experiment has been tried, can be made to vegetate at or below the freezing-point: yet this degree of cold does not injure the vegetating power of seeds; for many seeds will vegetate as well as ever after having been frozen, or after having been kept in frozen water. We may conclude, then, that a certain degree of heat is necessary for the germination of seeds. And every species of plants seems to have a degree peculiar to itself, at which its seeds begin to germinate; for every seed has a peculiar season at which it begins to germinate, and this season varies with the temperature of the air. Mr. Adanson found that seeds, when sown at the same time in France and in Senegal, always appeared sooner above ground in the latter country, where the climate is hotter, than in France.

Seeds, although supplied with moisture, and placed in a proper temperature, will not germinate, if atmospherical air is completely excluded from them. Mr. Ray found that grains of lettuce did not germinate in the vacuum of an air-pump, but they began to grow as soon as air was admitted to them. Homberg made a number of experiments on the same subject, which were published in the Memoirs of the French Academy for the year 1693. He found that the greater number of seeds which he tried refused to vegetate in the vacuum of an air-pump. Some, however, did germinate; but Boyle, Muschenbroek, and Boerhaave, who made experiments on the same subject in succession, proved beyond a doubt that no plant vegetates in the vacuum of an air-pump; and that in those cases in which Homberg's seeds germinated, the vacuum was far from perfect, a quantity of air still remaining in the receiver. It follows, therefore, that no seed will germinate unless atmospherical air, or some air having the same properties, has access to it. It is for this reason that seeds will not germinate at a certain depth below the surface of the earth.

Mr. Scheele found that beans would not germinate except oxygen gas was present. Mr. Achard afterwards proved that oxygen gas is absolutely necessary for the germination of all seeds, and that no seed will germinate in azotic gas, or hydrogen gas, or carbonic acid gas, unless these gases contain a mixture of oxygen gas. These experiments have been confirmed by Mr. Gough, Mr.

Cruikshank, and many other philosophers. It follows, therefore, that it is not the whole atmospherical air, but merely the oxygen gas which it contains, that is necessary for the germination of seeds.

Nay, M. Humboldt has ascertained that seeds vegetate more rapidly when steeped in oxymuriatic acid, or when watered with it; and this acid is well known for the facility with which it parts with oxygen. This acid seems even to augment the vegetative power of seeds. At Vienna several seeds which had been long kept, and which had constantly refused to germinate, grew readily when treated with this acid.

Light also has considerable influence on the germination of seeds. Ingenhousz found that seeds always germinate faster in the dark than when exposed to the light. His experiments were repeated by Mr. Sennebier with equal success. But the abbé Bertholin, who distinguished himself so much by his labours to demonstrate the effect of electricity on vegetation, objected to the conclusions of these philosophers; and affirmed that the difference in the germination of seeds in the shade and in the light was owing, not to the light itself, but to the difference of the moisture in the two situations; the moisture evaporating much faster from the seeds in the light than from those in the shade; and he affirmed, that when precautions were taken to keep the seeds equally moist, those in the sun germinated sooner than those in the shade. But when Mr. Sennebier repeated his former experiments, and employed every possible precaution to ensure the equality of moisture in both situations, he constantly found the seeds in the shade germinate sooner than those in the light. We may conclude, therefore, that light is injurious to germination; and hence one reason for covering seeds with the soil in which they are to grow.

Thus we have seen that seeds will not germinate unless moisture, heat, and oxygen gas, are present; and that they do not germinate well if they are exposed to the action of light. Now, in what manner do these substances affect the seed? What are the changes which they produce?

It was observed before, that all seeds have one or more cotyledons. These cotyledons contain a quantity of farinaceous matter, laid up on purpose to supply the embryo plant with food as soon as it begins to require it. This food, however, must undergo some previous preparation before it can be applied by the plant to the formation or completion of its organs. Now all the phenomena of germination, which we can perceive, consist in the chemical changes which are produced in that food, and the consequent development of the organs of the plant.

When a seed is placed in favourable circumstances, it gradually imbibes moisture, and very soon after emits a quantity of carbonic acid gas, even though no oxygen gas should be present. If no oxygen gas is present, the process stops here, and no germination takes place. But if oxygen gas is present, it is gradually absorbed by the seed; and at the same time the farina of the cotyledons assumes a sweet taste, resembling sugar: it is therefore converted into sugar, or some substance analogous to it. M. Sausure, jun. has ascertained that the quantity of oxygen gas absorbed during the germination

is always proportional to the carbonic acid gas emitted; that is, the carbonic acid emitted contains in it precisely the same quantity of oxygen as has been absorbed. Hence it is evident that the farina is changed into sugar by diminishing its carbon, and of course by augmenting the proportion of its hydrogen and oxygen. This is precisely the process of malting, or of converting grain into malt; during which it is well known that there is a considerable heat evolved; so much indeed, that in certain circumstances grain improperly kept has even taken fire. We may conclude from this, that during the germination of seeds in the earth there is also an evolution of a considerable portion of heat. This indeed might have been expected, as it usually happens when oxygen gas is absorbed.

So far seems to be the work of chemistry alone, at least we have no right to conclude that any other agent interferes; since hay, when it happens to imbibe moisture, exhibits nearly the same processes. Carbonic acid gas is evolved, oxygen gas is absorbed, heat is produced so abundantly that the hay often takes fire: at the same time a quantity of sugar is formed. It is owing to a partial change of the same kind that old hay generally tastes much sweeter than new hay. Now we have no reason to suppose that any agents peculiar to the vegetable kingdom reside in hay: as all vegetation, and all power of vegetating, are evidently destroyed.

But when the farina in the seeds of vegetables is converted into sugar, a number of vessels make their appearance in the cotyledon. These vessels may indeed be detected in many seeds before germination commences; but they become much more distinct after it has made some progress. Branches from them have been demonstrated by Grew, Malpighi, and Hedwig, passing into the radicle, and distributed through every part of it. These evidently carry the nourishment prepared in the cotyledons to the radicle; for if the cotyledons are cut off, even after the processes above described are completed, germination, as Bonnet and Sennebier ascertained by experiment, immediately stops. The food therefore is conveyed from the cotyledons into the radicle; the radicle increases in size, assumes the form of a root, sinks down into the earth, and soon becomes capable of extracting the nourishment necessary for the future growth of the plant. Even at this period, after the radicle has become a perfect root, the plant, as Sennebier ascertained by experiment, ceases to vegetate if the cotyledons are cut off. They are still then absolutely necessary for the vegetation of the plant.

The cotyledons now assume the appearance of leaves, and appear above the ground, forming what are called the seminal leaves of the plant. After this the plumula gradually increases in size, rises out of the earth, and expands itself into branches and leaves. The seminal leaves, soon after this, decay and drop off; and the plant carries on all the processes of vegetation without their assistance.

Mr. Eller attempted to shew that there is a vessel in seeds which passes from the cotyledons to the plumula; but later anatomists have not been able to perceive any such vessel. Even Mr. Hedwig, one of the most patient, acute, and successful philosophers that

ever examined the structure of vegetables, could never discover any such vessel, although he traced the vessels of the cotyledons even through the radicle. As it does not appear, then, that there is any communication between the cotyledons and the plumula, it must follow that the nourishment passes into the plumula from the radicle: and accordingly we see that the plumula does not begin to vegetate till the radicle has made some progress. Since the plant ceases to vegetate, even after the radicle has been converted into a root, if the cotyledons are removed before the plumula is developed, it follows that the radicle is insufficient of itself to carry on the processes of vegetation, and that the cotyledons still continue to perform a part. Now we have seen already what that part is; they prepare food for the nourishment of the plant. The root, then, is of itself insufficient for this purpose. When the cotyledons assume the form of seminal leaves, it is evident that the nourishment, which was originally laid up in them for the support of the embryo plant, is exhausted, yet they still continue as necessary as ever. They must therefore receive the nourishment which is imbibed by the root; they must produce some changes on it, render it suitable for the purposes of vegetation, and then send it back again to be transmitted to the plumula.

After the plumula has acquired a certain size, which must be at least a line, if the cotyledons are cut off, the plant, as Mr. Bonnet ascertained by a number of experiments, afterwards repeated with equal success by Mr. Sennebier, does not cease to vegetate, but it continues always a mere pigmy: its size, when compared with that of a plant whose cotyledons are allowed to remain, being only as 2 to 7.

When the plumula has expanded completely into leaves, the cotyledons may be removed without injuring the plant, and they very soon decay of themselves. It appears, then, that this new office of the cotyledons is afterwards performed by that part of the plant which is above ground.

Thus we have traced the phenomena of germination as far as they have been detected. The facts are obvious; but the manner in which they are produced is a profound secret. We can neither explain how the food enters into the vessels, how it is conveyed to the different parts of the plant, how it is deposited in every organ, nor how it is employed to increase the size of the old parts, or to form new ones. These phenomena are analogous to nothing in mechanics or chemistry, but resemble exactly the organization and nourishment of animals. They belong therefore to that difficult branch of science known by the name of physiology.

GERUND, in grammar, a verbal noun of the neuter gender, partaking of the nature of a participle, declinable only in the singular number, through all the cases except the vocative: as, nom. *amandum*, gen. *amandi*, dat. *amando*, accus. *amandum*, abl. *amando*.

GEROPOGON, a genus of the syngenesia polygamia aequalis class and order. The calyx is simple; recept. with bristle-shaped chaffs; seeds of the disk with feathered down, of the ray with five awns. There are three species, all plants of Italy, having the same habit with the tragopogons.

GESNERIA, a genus of the angiospermia

order, in the didynamia class of plants, and in the natural method ranking under the 40th order, personata. The calyx is quinquefid, and placed on the germen; the corolla incurved and then recurved; the capsule inferior and bilocular. There are 12 species, herbs and shrubs of the West Indies.

GETHYLLIS, a genus of the monogynia order, in the dodecandria class of plants, and in the natural method ranking under the 9th order, spathaceæ. The corolla is six-cleft, and the stamina are in six different directions; the capsule is trilocular. There are four species, herbs of the Cape.

GEUM, *avens*, or *herb-bennet*, a genus of the polygamia order, in the icosandria class of plants, and in the natural method ranking under the 35th order, senticosæ. The calyx is cleft into ten parts; there are five petals, and each of the seeds has a jointed awn. There are nine species; of which the most remarkable are,

1. The urbanum, with thick fibrous roots, of an aromatic taste: rough, serrated leaves; and upright, round, hairy stalks, terminated by large yellow flowers, succeeded by globular fruit.

2. The rivale, with a very thick, fleshy, and fibrous root, hairy leaves, and upright stalks 10 or 12 inches high, terminated by purple flowers nodding on one side. Of this there are varieties with red and with yellow flowers. Both these are natives of Britain, and are easily propagated either by the root or seed. The roots of the first, gathered in the spring before the stem comes up, and infused in ale, give it a pleasant flavour, and prevent its growing sour: infused in wine they have a stomachic virtue. The taste is mildly austere and aromatic, especially when the plant grows in warm dry situations; but in moist shady places it has little virtue. Cows, goats, sheep, and swine, eat the plant; horses are not fond of it. The powdered root of the second species will cure tertian agues, and is daily used for that purpose by the Canadians. Sheep and goats eat the plant; cows, horses, and swine, are not fond of it.

GHINIA, a genus of the diandria monogynia class and order. The calyx is five-toothed and acuminate; cor. two-lipped; stam. four, with two barren anthers at the shorter filaments; per. a drupe, containing a four or five-celled nut, with a seed in each cell. There are two species, annuals of the West Indies.

GIANTS-CAUSEWAY, a vast collection of basaltic pillars in the county of Antrim in Ireland. (See BASALTES.) The principal or grand causeway (for there are several less considerable and scattered fragments) consists of a most irregular arrangement of many hundred thousands of columns: almost all of them are of a pentagonal figure, but so closely and compactly situated on their sides, though perfectly distinct from top to bottom, that scarcely any thing can be introduced between them. The columns are of an unequal height and breadth; some of the highest, visible above the surface of the strand, and at the foot of the impending angular precipice, perhaps about 20 feet, they do not exceed this height, at least none of the principal arrangement. How deep they are fixed in the strand was never yet discovered. This grand arrangement extends nearly 200 yards, visible at

low water; how far beyond is uncertain: from its declining appearance, however, at low water, it is probable it does not extend under water to a distance any thing equal to what is seen above. The breadth of the principal causeway which runs out in one continued range of columns, is, in general, from 20 to 30 feet; at one place or two it may be nearly 40 for a few yards. In this account are excluded the broken and scattered pieces of the same kind of construction, that are detached from the sides of the grand causeway, as they do not appear to have ever been contiguous to the principal arrangement, though they have frequently been taken into the width; which has been the cause of such wild and dissimilar representations of this causeway, which different accounts have exhibited. The highest part of this causeway is the narrowest, at the very spot of the impending cliff whence the whole projects, where, for four or five yards, it is not above ten or fifteen wide. The columns of this narrow part incline from a perpendicular a little to the westward, and form a slope on their tops, by the unequal height of the columns on the two sides; by which an ascent is made at the foot of the cliff, from the head of one column to the next above, gradatim, to the top of the great causeway, which, at the distance of half a dozen yards from the cliff, obtains a perpendicular position, and, lowering in its general height, widens to about 20, or between 20 and 30 feet, and for 100 yards nearly is always above water. The tops of the columns for this length being nearly of an equal height, they form a grand and singular parade that may be easily walked on, rather inclining to the water's edge. But from high-water mark, as it is perpetually washed by the beating surges on every return of the tide, the platform lowers considerably, and becomes more and more uneven, so as not to be walked on but with the greatest care. At the distance of 150 yards from the cliff, it turns a little to the east for 20 or 30 yards, and then sinks into the sea. The figure of these columns is almost unexceptionably pentagonal, or composed of five sides; there are but very few of any other figure introduced: some few there are of three, four, and six sides, but the generality of them are five-sided, and the spectator must look very nicely to find any of a different construction: yet what is very extraordinary, and particularly curious, there are not two columns in ten thousand to be found, that either have their sides equal among themselves, or whose figures are alike. Nor is the composition of these columns or pillars less deserving the attention of the curious spectator. They are not of one solid stone in an upright position, but composed of several short lengths, curiously joined, not with flat surfaces, but articulated into each other like a ball and socket, or like the joints in the vertebrae of some of the larger kind of fish, the one end at the joint having a cavity into which the convex end of the opposite is exactly fitted. This is not visible but by disjoining the two stones. The depth of the concavity or convexity is generally about two or three inches. And what is still farther remarkable of the joint, the convexity, and the correspondent concavity, are not conformed to the external angular figure of the column, but exactly round, and as large as the size or diameter of the co-

lumn will admit; and consequently as the angles of these columns are in general extremely unequal, the circular edges of the joint are seldom coincident with more than two or three sides of the pentagonal, and from the edge of the circular part of the joint to the exterior sides and angles they are quite plain. It is still farther very remarkable likewise, that the articulations of these joints are frequently inverted; in some the concavity is upwards, in others the reverse. This occasions that variety and mixture of concavities and convexities on the tops of the columns, which is observable throughout the platform of this causeway, yet without any discoverable design or regularity with respect to the number of either. The length also of these particular stones, from joint to joint, is various: in general they are from 18 to 24 inches long; and, for the most part, longer towards the bottom of the columns than nearer the top, and the articulation of the joints something deeper. The size or diameter likewise of the columns is as different as their length and figure; in general they are from 15 to 20 inches in diameter. There are no traces of uniformity or design discovered throughout the whole combination, except in the form of the joint, which is invariably by an articulation of the convex into the concave of the piece next above or below it; nor are there any traces of a finishing in any part, either in height, length, or breadth, of this curious causeway. If there is here and there a smooth top to any of the columns above water, there are others just by, of equal height, that are more or less convex or concave, which show them to have been joined to pieces that have been washed, or by other means taken off. And undoubtedly those parts that are always above water have, from time to time, been made as even as might be; and the remaining surfaces of the joints must naturally have been worn smoother by the constant friction of weather and walking, than where the sea, at every tide, is beating upon it, and continually removing some of the upper stones, and exposing fresh joints. And farther, as these columns preserve their diameters from top to bottom, in all the exterior ones, which have two or three sides exposed to view, the same may with reason be inferred of the interior columns whose tops only are visible. Yet, what is very extraordinary and equally curious in this phenomenon is, that notwithstanding the universal dissimilitude of the columns, both as to their figure and diameter, and though perfectly distinct from top to bottom, yet is the whole arrangement so closely combined at all points, that hardly a knife can be introduced between them either upon the sides or angles. And it is a most curious entertainment to examine the close contexture and nice insertion of such an infinite variety of angular figures as are exhibited on the surface of this grand parade. From the infinite dissimilarity of the figure of these columns, this will appear a most surprising circumstance to the curious spectator; and would incline him to believe it a work of human art, was it not, on the other hand, inconceivable that the genius or invention of man should construct and combine such an infinite number of columns, which should have a general apparent likeness, and yet be so universally dissimilar in their figure, as

that, from the minutest examination, not two in ten or twenty thousand should be found whose angles and sides are equal among themselves, or of the one column to those of the other. That it is the work of nature there can be no doubt to an attentive spectator, who carefully surveys the general form and situation, with the infinitely various configuration of the several parts of this causeway. There are no traces of regularity or design in the outlines of this curious phenomenon; which, including the broken and detached pieces of the same kind of workmanship, are extremely scattered and confused; and, whatever they might be originally, do not at present appear to have any connection with the grand or principal causeway, as to any supposable design or use in its first construction, and as little design can be inferred from the figure or situation of the several constituent parts. The whole exhibition is, indeed, extremely confused, ununiform, and destitute of every appearance of use or design in its original construction. But what, beyond dispute, determines its original to have been from nature is, that the very cliffs, at a great distance from the causeway, especially in the bay to the eastward, exhibit at many places the same kind of columns, figured and jointed in all respects like those of the grand causeway: some of them are seen near to the top of the cliff, which, in general, in these bays to the east and west of the causeway, is near 300 feet in height; others again are seen about midway, and at different elevations from the strand. A very considerable exposure of them is seen in the very bottom of the bay to the eastward, near 100 rods from the causeway, where the earth has evidently fallen away from them upon the strand, and exhibits a most curious arrangement of many of these pentagonal columns, in a perpendicular position, supporting, in appearance, a cliff of different strata of earth, clay, rock, &c. to the height of 150 feet or more, above. Some of these columns are between 30 and 40 feet high, from the top of the sloping bank below them; and being longest in the middle of the arrangement, shortening on either hand in view, they have obtained the appellation of organs, from a rude likeness in this particular to the exterior or frontal tubes of that instrument; and as there are few broken pieces on the strand near it, it is probable that the outside range of columns that now appears is really the original exterior line, toward the sea, of this collection. But how far they extend internally into the bowels of the incumbent cliff is unknown. The very substance, indeed, of that part of the cliff which projects to a point, between the two bays on the east and west of the causeway, seems composed of this kind of materials; for, besides the many pieces that are seen on the sides of the cliff that circulate to the bottom of the bays, particularly the eastern side, there is, at the very point of the cliff, and just above the narrow and highest part of the causeway, a long collection of them seen, whose heads or tops just appearing without the sloping bank, plainly show them to be in an oblique position, and about half-way between the perpendicular and horizontal. The heads of these, likewise, are of mixed surfaces, convex and concave, and the columns evidently appear to have been removed from

their original upright, to their present inclining or oblique position, by the sinking or falling of the cliff.

GIBBOUS, in astronomy, a term used in reference to the enlightened parts of the moon, whilst she is moving from the first quarter to the full, and from the full to the last quarter: for all that time the dark part appears horned or falcated, and the light one convex or gibbous.

GIBELINS, or **GIBELLINS**, a famous faction in Italy, opposite to another, called the **Guelphs**.

These two factions ravaged and laid waste Italy for a long series of years, so that the history of that country, for the space of two centuries, is no more than a detail of their mutual violences and slaughters. The Gibelins adhered to the emperor against the pope: but concerning their origin, and the reason of their names, we have but a very obscure account. According to the generality of authors, they rose about the year 1240, upon the emperor Frederic II.'s being excommunicated by pope Gregory IX. Other writers maintain, that the two factions arose ten years before, though still under the same pope and emperor. But the most probable opinion is that of Maimbourg, who says, that the two factions of Guelphs and Gibelins arose from a quarrel between two antient and illustrious houses on the confines of Germany, that of the Henries of Gibeling, and that of the Guelphs of Adorf.

GIFT, a transferring the property in a thing from one to another without a valuable consideration; for to transfer any thing upon a valuable consideration is a contract or sale; he who gives any thing is called the donor; and he to whom it is given is called the donee.

By the common law all chattels, real or personal, may be granted or given, without deed, except in some special cases; and a free gift is good without a consideration, if not to defraud creditors. Park. 57.

But no leases, estates, or interests, either of freehold, or term of years, or any uncertain interest, not being copyhold or customary interest, of, in, to, or out of, any messuage, manors, lands, tenements, or hereditaments, shall at any time be assigned, granted, or surrendered, unless it is by deed or act in writing, signed by the party so assigning, granting, or surrendering the same, or their agents thereunto lawfully authorised by writing, or by act and operation of law. 29 Car. II. c. 3.

A gift of any thing without a consideration, is good: but it is revocable before delivery to the donee, of the thing given. Jenk. 109 pl. 9.

GILBERTINES, a religious order founded in England by St. Gilbert, in the reign of Henry I. The nuns followed the rule of St. Benedict, and the monks that of St. Augustin. There were many monasteries of this order in different parts of England.

GILD. See **GELD**.

GILD MERCHANT, was a certain privilege or liberty granted to merchants, whereby they were enabled, among other things, to hold certain pleas of land within their own precincts; as the gild-merchant granted by king John to the burgesses of Nottingham.

GILDING, is the application of gold to the surfaces of bodies: it is of two principal kinds, according to the method of applying the gold.

Wood, leather, paper, and similar substances, are gilt by fastening on leaves of gold by means of some cement. But metals are gilt by a chemical application of the gold to the surface. This last is called water-gilding.

The gilding of wood, and similar substances, is of three kinds: oil-gilding, burnished gilding, and japanners' gilding, which we shall severally describe, after noticing the materials and tools necessary for the operations.

Of gold-leaf.—There are three kinds of gold-leaf in common use. Pure gold-leaf, which is made by hammering gold till it is sufficiently thin (see GOLD-BEATING). Pale leaf-gold, which has a greenish colour, and is made in the same way of gold alloyed with silver. Dutch gold, which is brought from Holland, and is in fact only copper-leaf coloured by the fumes of zinc. It is much cheaper than true leaf-gold, and is very useful where large quantities of gilding are wanted, which can be defended from the weather, and where great nicety is not required; but it changes its colour entirely when exposed to moisture; and indeed, in all cases, its beauty is soon impaired, unless well secured by varnish. It is therefore only a cheap substitute for true gold-leaf, which may be useful where durability is not an object.

Of the instruments necessary for gilding.—The first instrument is the cushion, for receiving the leaves of gold from the books in which they are bought. It is made by covering a board of about eight inches square, with a double thickness of flannel: and over that a piece of buff leather, and fastening it tight round the edges.

The knife for cutting the leaves into the requisite sizes should be made like a pallet-knife, and should not have its edge too sharp.

The tip is a tool made by fastening the long hairs of a squirrel's tail between two cards; and is used for taking up the gold-leaf after it is cut, and applying it to the article to be gilded.

A fitch pencil is used for the same purpose as the last, in taking up very small bits of gold-leaf. A ball of cotton is necessary for pressing down the leaf, after it is laid on. A large camel's-hair brush is used for dusting the work, and clearing away the superfluous gold.

Oil-gilding.—First prime your work with boiled linseed-oil and white-lead; and when that is dry, cover it over with a thin coat of gold size, made of stone-ochre ground in fat oil. When that is so dry as to feel clammy to the fingers, or to be what the gilders call tacky, it is fit for gilding. Having spread your leaves upon the cushion, cut them into slips of the proper width for covering your work. Then breathe upon your tip, which, by moistening it, will cause it to take up the leaves from the cushion. Having applied them by the tip on the proper parts of your work, press them down by the ball of cotton. Observe to repair, by putting small pieces of gold on, any parts which you have omitted to cover. When all your work is sufficiently covered, let it dry, and clean it off with the brush.

This sort of gilding is the easiest, least expensive, and stands the weather best, and may be cleaned with a little water at any

time; but wants the lustre of burnished gilding.

Burnished gilding.—This is the sort of gilding generally used for picture-frames, looking-glasses, &c.

The wood intended to be gilt in this manner, should first be well sized, and then covered with seven or eight coats of size and whiting, so as to form a body of considerable thickness. Having got a sufficient quantity of whiting upon the work, it must be carefully cleaned, taking care to free all the cavities and hollows from the whiting that may have choked them up, and by proper moulds and tools restoring the sharpness of the mouldings intended to be shewn.

It is then to receive a coat of size, which is made by boiling armenian bole with parchment size. This must also remain till it is sufficiently dry for gold. It must not be quite dry, therefore it would not be prudent to lay on more at a time than can be gilt before it becomes too dry.

The work being thus prepared, place it a little declining from you; and having ready a cup of clean water, and some hair-pencils, moisten a part of the work, and then apply the gold by the tip to the moistened part. The gold will immediately adhere close to the work: proceed to wet the next part, and apply the gold as before, repeating this operation till the whole is completed; taking care not to let any drops of water come upon any part of the gold already laid on. Care should therefore be taken that no part be missed in going over it at first, as it is not so easily mended as the oil-gilding.

The work being thus gilt, it is suffered to remain about 24 hours; when the parts that are designed to be burnished, are polished with a dog's tooth, or, what is better, with an agate burnisher. The gilding must not be quite dry when burnished; there is a state proper for the purpose, which is only to be known by experience.

Japanners' gilding.—The gilding of japanned work consists in drawing with a hair-pencil, in gold size, the intended ornaments, and afterwards applying gold-leaf, or gold powder.

The gold size may be prepared in the following manner: Take of linseed-oil, and of gum animi, four ounces. Set the oil to boil in a proper vessel, and then add the gum animi gradually in powder, stirring each quantity about in the oil till it appears to be dissolved, and then putting in another, till the whole is mixed with the oil. Let the mixture continue to boil, till, on taking a small quantity out, it appears of a thicker consistence than tar, and then strain the whole through a coarse cloth, and keep it for use; but it must, when applied, be mixed with vermilion and oil of turpentine.

Having laid on the gold size, and suffered it to dry, the gold-leaf is applied in the usual way; or if it is not wanted to shine so much, gold powder is applied, which is made by grinding gold-leaf upon a stone with honey, and afterwards washing the honey away with water. If the gilding is to be varnished over, Dutch gold may be used, or aurum musivum may be used instead of real gold powder.

To write on paper with letters of gold.—Put some gum arabic into common writing-ink, and write with it in the usual way. When the writing is dry, breathe on it; the

warmth and moisture soften the gum, and will cause it to fasten on the gold-leaf; which may be laid on in the usual way, and the superfluous part brushed off. Or instead of this, any japanners' size may be used.

To lay gold upon white earthenware, or glass.—Procure some japanners' gold size, and with it draw your design upon the vessel to be gilt, moistening the gold size, as you find necessary, with oil of turpentine. Set your work in a clean place to dry, for about an hour, and then place it so near the fire, that you could but just bear the heat of it with your hand for a few seconds. Let it remain there till it feels quite tacky or clammy; then, having procured a cushion, and some leaf-gold, cut it into slips of the proper size, and lay it on with the little cotton ball. When the gold is all on, put the ware into an oven to be baked for two or three hours.

Glasses, &c. may also be gilt, by drawing the figures with shell gold mixed with gum arabic, and a little borax. Then apply sufficient heat to it; and, lastly, burnish it.

Gilding on glass or porcelain, by burning in.—Dissolve gold in aqua regia, and evaporate the acid by heat, you will obtain a gold powder; or precipitate the gold from the solution by pieces of copper. Lay this gold on with a strong solution of borax and gum water, and it will be ready for burning-in.

Gilding metals.—One method of applying gold upon metals is by first cleaning the metal to be gilt; then gold-leaf is laid on it, which, by means of rubbing with a polished blood-stone, and a certain degree of heat, are made to adhere perfectly well. In this manner silver-leaf is fixed and burnished upon brass, in the making of what is called French plate; and sometimes also gold-leaf is burnished upon copper and iron.

Gilding by amalgamation. A better method is, by previously forming the gold into paste, or amalgam, with mercury.

In order to obtain an amalgam of gold and mercury, the gold is first to be reduced into thin plates or grains, which are heated red-hot, and thrown into mercury previously heated, till it begins to smoke. Upon stirring the mercury with an iron rod, the gold totally disappears. The proportion of mercury to gold is generally as six or eight to one.

The method of gilding by amalgamation is chiefly used for gilding copper, or an alloy of copper, with a small portion of zinc, which more readily receives the amalgam, and is also preferable on account of its colour, which more resembles that of gold than the colour of copper.

When the metal to be gilt is wrought or chased, it ought to be previously covered with quicksilver before the amalgam is applied, that this may be easier spread; but when the surface of the metal is plane, the amalgam may be directly applied to it.

The metal required to be gilt is first rubbed over with a little aquafortis, by which the surfaces cleaned from any rust or tarnish that might prevent the union of the two metals. The amalgam being then equally spread over the surface by means of a brush, the mercury is evaporated by a heat just sufficient for that purpose; for if it is too great, part of the gold may also be expelled, and part of it will run together, and leave some of the sur-

face of the metal bare. While the mercury is evaporating the piece is to be, from time to time, taken from the fire, that it may be examined; that the amalgam may be spread more equally by means of a brush; that any defective parts of it may be again covered, and that the heat may not be too suddenly applied to it. When the mercury is evaporated, which is known by the surface becoming entirely of a dull-yellow colour, the metal must then undergo other operations, by which the fine gold-colour is given to it.

First, the gilded piece of metal is rubbed with a scratch-brush (which is a brush composed of brass wire) till its surface is made smooth; then it is covered over with a composition called gilding-wax, and is again exposed to the fire till the wax is burnt off. This wax is composed of bee's-wax, frequently mixed with some of the following substances: red ochre, verdigris, copper scales, alum, vitriol, borax; but, according to Dr. Lewis, the saline substances are sufficient, without any wax.

By this operation the colour of the gilding is heightened; and the effect seems to be produced by a perfect dissipation of some mercury remaining after the former operation.

The gilt surface is then covered over with a saline composition, consisting of nitre, alum, or vitriolic salt, ground together, and mixed up into a paste with water or urine. The piece of metal thus covered is exposed to a certain degree of heat, and then quenched in water. By this method its colour is further improved, and brought nearer to that of gold. This effect seems to be produced by the acid of the nitre (which is disengaged by the sulphuric acid of the alum, during the exposure to heat) acting upon any particles of copper which may happen to lie upon the gilded surface.

Lastly, Some artists think that they give an additional lustre to their gilt work, by dipping it in a liquor prepared by boiling some yellow materials, as sulphur, orpiment, or turmeric. The only advantage of this operation is, that part of the yellow matter remains in some of the hollows of the carved work, in which the gilding is apt to be more imperfect, and to which it gives a rich and solid appearance.

It may here be noticed, that the use of the aquafortis or nitric acid, mentioned in the beginning of the process, is not, as is generally supposed, confined merely to cleansing the surface of the metal to be gilt from rust or tarnish; but it also greatly facilitates the application of the amalgam to the surface of that metal, probably in the following manner: It first dissolves part of the mercury of the amalgam; and when the solution is applied to the copper, this latter metal, having a stronger disposition to unite with the nitrous acid than the mercury has, precipitates the mercury upon its surface, in the same manner as a polished piece of iron precipitates upon its surface copper from a solution of blue vitriol. When the metal to be gilt is thus covered with a thin coat of precipitated mercury, it readily receives the amalgam.

On the subject of gilding by amalgamation, Dr. Lewis has the following remarks: "There are two principal inconveniences in this business; one, that the workmen are exposed to the fumes of the mercury, and generally, sooner or later, have their health

greatly impaired by them; the other, the loss of the mercury; for though part of it is said to be detained in the cavities made in the chimneys for that purpose, yet the greatest part of it is lost. From some trials I have made, it appeared that both these inconveniences, particularly the first and most considerable one, might be in a good measure avoided, by means of a furnace of a due construction."

If the communication of a furnace with its chimney, instead of being over the fire, is made under the grate, the ash-pit door, or other apertures beneath the grate, closed, and the mouth of the furnace left open, the current of air, which otherwise would have entered beneath, enters now at the top, and passing down through the grate to the chimney, carries with it completely both the vapour of the fuel, and the fumes of such matters as are placed upon it. The back part of the furnace should be raised a little higher above the fire than the fore part, and an iron plate laid over it, that the air may enter only at the front, where the workman stands, who will be thus effectually secured from the fumes, and from being incommoded by the heat, and at the same time have full liberty of introducing, inspecting, and removing, the work.

If such a furnace is made of strong forged (not milled) iron plate, it will be sufficiently durable. The upper end of the chimney may reach above a foot and a half higher than the level of the fire; over this is to be placed a larger tube, leaving an interval of an inch, or more, all round between it and the chimney, and reaching to the height of ten or twelve feet; the higher the better. The external air, passing up between the chimney and the outer pipe, prevents the latter from being much heated, so that the mercurial fumes will condense against its sides into running quicksilver, which falling down to the bottom, is there caught in a hollow rim, formed by turning inwards a portion of the lower part, and conveyed by a pipe at one side into a proper receiver.

Gilding iron or steel. In gilding iron or steel by means of an amalgam, as the metal has no affinity for the mercury, an agent must be employed to dispose the surface to receive the gilding. For this purpose a solution of mercury in nitrous acid (aquafortis), or what the workmen call quicksilver-water, is applied to the parts intended to be gilded; the acid, by a stronger affinity, seizes on a portion of the iron, and deposits in the place of it a thin coating of mercury, which will not refuse an union afterwards with the gold amalgam that may be applied; but by this process the surface of the metal is injured by the nitrous acid, and the union of the mercury is very slight, so that a bright and durable gilding cannot be obtained.

Another method. Sometimes a solution of blue vitriol is applied, with a camel's-hair pencil, to the parts of the steel intended to be gilt. By a chemical action, exactly similar to what we have described as taking place when a solution of nitrate of mercury is employed, a thin coating of copper is precipitated on the metal. Copper having an affinity for mercury, a kind of union may by this means be effected between the amalgam and the iron or steel, as the case may be. In whichever of these methods the amalgam is

brought into union with the steel, the surface is injured by the action of the acid employed, and still a heat sufficient to volatilize the mercury must be afterwards used.

Gilding of iron by heat. When the surface is polished bright, it must be heated till it becomes blue. Gold leaf is then applied to its surface, and burnished down. It is then heated again, and another layer of gold burnished on it. In this manner three or four coats are given, according to the strength of the gilding intended. This is a more laborious process than the two last, but it is not attended with so much risk.

An improved process for gilding iron or steel. This process, which is less known among artists than it deserves to be, may prove useful to those who have occasion to gild iron or steel. The first part of the process consists in pouring over a solution of gold in nitro-muriatic acid (aqua regia) about twice as much ether, which must be done with caution, and in a large vessel. These liquids must then be shaken together; as soon as the mixture is at rest, the ether will be seen to separate itself from the nitro-muriatic acid, and to float on the surface. The nitro-muriatic acid becomes more transparent, and the other darker than they were before; the reason of which is, that the ether has taken the gold from the acid. The whole mixture is then to be poured into a glass funnel, the lower aperture of which is small; but this aperture must not be opened till the fluids have completely separated themselves from each other. It is then to be opened; by which means the liquid which has taken the lowest place by its greater gravity, viz. the nitro-muriatic acid, will run off; after which, the aperture is to be shut, and the funnel will then be found to contain nothing but ether mixed with the gold, which is to be put into well-closed bottles, and preserved for use. In order to gild iron or steel, the metal must be first well polished with the finest emery, or rather with the finest crocus martis or colcothar of vitriol, and common brandy. The auriferous ether is then to be applied with a small brush; the ether soon evaporates, and the gold remains on the surface of the metal. The metal may then be put into the fire, and afterwards polished. By means of this auriferous ether, all kinds of figures may be delineated on iron, by employing a pen, or fine brush. It is in this manner, we believe, that the Sohlinger sabre-blades are gilded.

Instead of ether, the essential oils may be used, such as oil of turpentine, or oil of lavender, which will also take gold from its solution.

Gilding of silver. Dissolve gold in the nitro-muriatic acid, and dip some linen rags in the solution; then burn them, and carefully preserve the ashes, which will be very black, and heavier than common. When any thing is to be gilded, it must be previously well burnished; a piece of cork is then to be dipped, first into a solution of salt in water, and afterwards into the black powder; and the piece, after being rubbed with it, must be burnished. This powder is frequently used for gilding delicate articles of silver.

Gilding of brass and copper. Fine instruments of brass, in order that their surface may be kept longer clean, may be gilded in the following manner.

Provide a saturated solution of gold, and having evaporated it to the consistence of oil, suffer it to shoot into crystals. These crystals must then be dissolved in pure water, and the articles to be gilded being immersed in it, are then to be washed in pure water, and afterwards burnished. This process may be repeated several times, till the articles have been well gilt. A solution of gold crystals is preferred to a mere solution of gold, because in the latter there is always a portion of free acid, which will not fail to exercise more or less action on the surface of the brass or copper, and injure its polish.

Grecian gilding. Dissolve some mercury in muriatic acid (spirit of salt), which will give a muriate of mercury. Mix equal parts of this and sal ammoniac, and dissolve them in aquafortis. Put some gold into this, and it will dissolve. When this is applied to silver, it becomes black; but by heating, it assumes the appearance of gilding.

To make shell-gold. Grind up gold-leaf with honey in a mortar; then wash away the honey with water, and mix the gold powder with gum water. This may be applied to any article with a camel's-hair pencil, in the same way as any other colour.

GILT-HEAD. See SPARUS.

GIMBALS, a contrivance by means of which barometers, vessels of oil, mariner's compasses, &c. may be suspended so as to arrange their upper parts horizontally. The nature of this contrivance will be at once understood by shewing its application to a mariner's compass. It consists of a hoop or ring supported upon two pins diametrically opposite each other, and issuing from the external surface of the ring in such a direction that both lie in the same diametrical line. When the hoop is suspended on these pins, it is at liberty to turn freely about the diameter, of which they constitute the prolongation. The notches or holes of support are disposed horizontally. The compass-box itself is placed in a similar ring with two projecting pivots; and these pivots are inserted in holes made in the former ring at equal distances from each of its pivots. If therefore the whole is left at liberty, the compass-box may vibrate upon the diametral line of the outer ring, as well as upon a line formed by its own pivots, at right angles to that diametral line. The consequence of this arrangement is, that the centre of gravity of the compass-box will dispose itself immediately beneath the intersection of both lines on which it is at liberty to move: that is, if the weight of the box and its component parts are properly disposed, the compass will assume a position in which the surface shall be horizontal.

GIN. See DISTILLATION.

GIN, in mechanics, a machine for driving piles, fitted with a windlass and winches at each end, where eight or nine men heave, and round which a rope is reeved, that goes over the wheel at the top: one end of this rope is seized to an iron monkey, that hooks to a beetle of different weights, according to the piles they are to drive, being from eight to thirteen hundred weight; and when hove up to a cross-piece near the wheel it un-hooks the monkey, and lets the beetle fall on the upper end of the pile, and forces the

same into the ground; then the monkey's own weight overhauls the windlass, in order for its being hooked again to the beetle.

GINANNIA, a genus of the class and order enneandria monogynia. The calyx is double, both one-leaved; petals three-fringed and spreading; germ pedicelled, with a membranaceous wing at top. Legume. There is one species, a shrub of Guiana.

GINKGO, or maidenhair-tree, of the dioecia class (order and character unknown), a large tree of Japan, with leaves resembling the adiantum, whence its popular name.

GINORA, a genus of the dodecandria monogynia class and order. The calyx is six-cleft; petals six; capsules one-seeded, four-celled, four-valved, coloured, many seeds. There is one species, an elegant shrub of Cuba, bearing handsome large red flowers.

GINGER. See AMOMUM.

GINSENG. See PANAX.

GIRDERS, in architecture, some of the largest pieces of timber in a floor.

By the building act, no girder is to lie less than 10 inches into the wall, and the ends to be laid in loam.

GIRDING-GIRT, in the sea language. A ship is girt, or has a girding-girt, when her cable is so tight or strained, upon the turning of the tide, that she cannot get over it, but lies across the tide.

GIRONNE, or **GIRONNY**, in heraldry, a coat of arms divided into girones or triangular figures, meeting in the centre of the shield, and alternately colour and metal.

GISEKIA, a genus of the class and order pentandria pentagynia. The calyx is five-leaved; corolla none; capsules five, approximating, roundish, one-seeded. There is one species, an annual of the East Indies.

GLABRASIA, a genus of the class and order polyadelphia polyandria. The calyx is five-cleft; nectarium composed of bristles; stamina 30, always in sixes; perianthium a drupe. There is one species, a large tree of the East Indies.

GLACIES MARIE. See MICA.

GLACIS, in fortification, that mass of earth which serves as a parapet to the covered way, sloping easily towards the campaign or field. See FORTIFICATION.

GLADIATORS, in antiquity, persons who fought generally in the arena at Rome, for the entertainment of the people.

The gladiators were usually slaves, and fought out of necessity, though sometimes freemen made profession of it, like our prize-fighters, for a livelihood. The Romans borrowed this cruel diversion from the Asiatics. They were all first sworn that they would fight till death; and if they failed they were put to death either by fire, swords, clubs, whips, &c. It was usual with the people or emperor to grant them life when they shewed no signs of fear. Augustus decreed that it should always be granted them.

After the engagement, several marks of favour were conferred on the victor, particularly a branch of palm-tree; and often a sum of money, perhaps gathered up among the spectators; but the most common rewards were the pileus and the rudis; the former being given only to such gladiators as were slaves, for a token of obtaining their

freedom, but the rudis seems to have been bestowed both on slaves and freemen, with this difference, that it procured the former no more than a discharge from any further performance in public: the rudis, when given to such persons as, being free, had hired themselves out for these shows, restored them to a full enjoyment of their liberty.

From slaves and freedmen, the wanton sport spread to persons of rank, as we find in Nero's time. And Domitian exhibited combats of women in the night-time. We also read that dwarfs encountered with one another. Constantine the Great first prohibited these combats in the East; but the practice was not entirely abolished in the West before Theodoric king of the Ostrogoths, in the year 500.

The dying GLADIATOR, is a most valuable monument of antient sculpture, which is now preserved in the palace of Chigi. This man, when he had received the mortal stroke, is particularly careful *ut procumbat honestè*, that he might fall honourably. He is seated in a reclining posture on the ground, and has just strength sufficient to support himself on his right arm; and in his expiring moments it is plainly seen that he does not abandon himself to grief and dejection, but is solicitous to maintain that firmness of aspect which the gladiators valued themselves on preserving in this season of distress, and that attitude which they had learnt of the masters of defence. He fears not death, nor seems to betray any tokens of fear by his countenance, nor to shed one tear. We see, in this instance, notwithstanding his remaining strength, that he has but a moment to live; and we view him with attention, that we may see him expire and fall. Thus the antients knew how to animate marble, and to give it almost every expression of life.

GLADIOLUS, *corn-flag*, a genus of the monogynia order, in the triandria class of plants, and in the natural method ranking under the sixth order, ensatæ. The corolla is sexpartite and ringent, the stamina ascending and bending upwards. There are thirty species, of which the most generally known is the communis or common gladiolus. This has a round, compressed, tuberous root, long sword-shaped leaves, an erect flower-stalk, two or three feet high, the top adorned with several pretty large flowers of a red or white colour, having each six petals. They appear in May and June, and are succeeded by plenty of seed in August. The plants are very hardy, and will thrive in any soil or situation. They are propagated by offsets from the roots. The gladiolus cardinalis is a bulb of the Cape, exquisitely beautiful.

GLAMA. See CAMELUS.

GLAND. See ANATOMY.

GLANDERS. See FARRIERY.

GLAREOLA, in ornithology, a genus of birds of the order of grallæ. The generic character is: bill strong, short, straight, hooked at the tip; nostrils at the base of the bill linear, oblique; gape of the mouth large; feet four-toed; toes long, slender, connected at the base by a membrane; tail forked, consisting of 12 feathers. There are three species. The austriaca inhabits the heaths of Europe near the banks of rivers, is about nine inches long, feeds on worms and aquatic insects, is very restless and clamorous. See

Plate Nat. Hist. fig. 214. The *senegallensis* is found near the Senegal, and in several parts of Siberia; and the *navia* is to be met with only in Germany.

GLASS, a transparent, brittle, factitious body, produced by the action of fire upon a fixed salt and sand, or stone, that readily melts.

The fixed alkalies have a strong affinity for several of the earths, particularly for silica and alumina, which they dissolve in considerable quantity, when assisted by heat. When a strong heat is applied to a mixture of fixed alkali and silica, it melts, and forms a transparent mass well known by the name of glass.

The method of making this useful compound was known at an early period. According to Pliny, the discovery was owing to an accident. Some merchants, with a ship-load of soda from Egypt, had cast anchor at the mouth of the river Belus in Phœnicia, and were dressing their dinner on the sand. They made use of large lumps of soda to support their kettles, and lighted fires under them. The heat melted the soda and the siliceous sand together, and the result was glass.

For some time after this accidental discovery, the manufacture of glass was confined to the river Belus. This manufacture seems to have been carried to a considerable degree of perfection among the ancients. They mention drinking-glasses, glass prisms, and coloured glasses of various kinds. But perfectly transparent glass was considered as very valuable; for Nero gave 50,000*l.* for two glass cups with handles; a proof that their processes must have been far less perfect than ours. It was usual for them to melt the materials of their glass into a black mass called ammonitrum, of which statues were sometimes made. This ammonitrum was again melted and purified by refiners. Glass panes seem to have been first used in windows in the third century; but they did not come into common use till long after.

The materials employed in the manufacture of glass may be reduced under three classes, namely, alkalies, earths, and metallic oxides.

The fixed alkalies may be employed indifferently; but soda is preferred in this country. The soda of commerce is usually mixed with common salt, and combined with carbonic acid. It is proper to purify it from both of these foreign bodies before using it. This, however, is seldom done.

The earths are silica, lime, and sometimes a little alumina. Silica constitutes the basis of glass. It is employed in the state of fine sand or flints; and sometimes for making very fine glass, rock crystal is employed. When sand is used, it ought if possible to be perfectly white; for when it is coloured with metallic oxides, the transparency of the glass is injured. Such sand can only be employed for very coarse glasses. It is necessary to free the sand from all the loose earthy particles with which it may be mixed, which is done by washing it well with water.

Lime renders glass less brittle, and enables it to withstand better the action of the atmosphere. It ought in no case to exceed the twentieth part of the silica employed, otherwise it corrodes the glass pots. This

indeed may be prevented by throwing a little clay into the melted glass; but in that case a green glass only is obtained.

The metallic oxides employed are the red oxide of lead or litharge, and the white oxide of arsenic. The red oxide of lead, when added in sufficient quantity, enters into fusion with silica, and forms a glass without the addition of any other ingredient. Five parts of minium and two of silica form a glass of an orange-colour and full of striae. Its specific gravity is 5. The red oxide of lead renders glass less brittle and more fusible; but when added beyond a certain proportion, it injures the transparency and the whiteness of glass.

The white oxide of arsenic answers the same purposes with that of lead; but on account of its poisonous qualities it is seldom used. It is customary to add a little nitre to the white oxide of arsenic, to prevent the heat from reviving it, and rendering it volatile. When added beyond a certain proportion, it renders glass opaque and milky like the dial-plate of a watch. When any combustible body is present, it is usual in some manufactures to add a little white oxide of arsenic. This supplying oxygen, the combustible is burnt, and flies off; while the revived arsenic is at the same time volatilized.

After mixing the alkali and sand together, it is usual to expose them for some time to a moderate heat. This serves several purposes. It drives off all combustible bodies which may happen to be mixed with the sand; it produces a commencement of combination which makes the glass afterwards less liable to corrode the clay pots in which it is melted; and the alkali, by this incipient combination, is not so apt to be volatilized, which might be the case if the materials were exposed at once to a violent heat. The mixture, after being thus heated, is called the frit. Through the domes in which the frit is heated, it is usual to see very thin bubbles of glass passing; a proof that some of the materials are volatilized during this first part of the process.

The frit, while still hot, is introduced into large pots made of a mixture of pure clay and baked clay, and exposed to a heat sufficient to melt it completely. The fusion must be continued till the effervescence occasioned by the separation of the carbonic acid from the soda has subsided, and the opaque scum, known by the name of glass-gall, which collects on the surface of the glass, must be removed. This scum is occasioned by the common salt and other foreign bodies which are always mixed with the soda of commerce. When the fusion has been continued the proper time, the furnace is allowed to cool a little. In that state the glass is exceedingly ductile, and readily assumes any shape that the workman pleases.

If the glass vessels, after being formed, were cooled rapidly, they would contract unequally, and become in consequence so brittle as to fall to pieces whenever they were handled. To prevent this inconvenience, they are put into a large red-hot furnace, which is allowed to cool very slowly to the temperature of the air. This process is called annealing.

The properties that distinguish good glass are well known. It is perfectly transparent;

its hardness is very considerable; its specific gravity varies from 2.3 to 4, according to the proportion of metallic oxide which it contains. When cold it is brittle; but at a red heat it is one of the most ductile bodies known, and may be drawn out into threads so fine as to be scarcely visible to the naked eye. (See DUCTILITY.) It is almost perfectly elastic, and of course is one of the most sonorous of bodies. There are but few chemical agents which have any action on it. Fluoric acid dissolves it with great rapidity, and so do the fixed alkalies when assisted by heat. Dr. Priestley has shown also, that the long-continued action of hot water is capable of decomposing it; a discovery which explains sufficiently the siliceous earth obtained by Boyle and Margraff, when they subjected water to tedious distillations in glass vessels.

There are different kinds of glass manufactured for different purposes: the principal of these are flint glass, crown glass, and bottle glass.

Flint glass is formed of soda, pounded flints, and oxide of lead. It is the densest, most transparent, and most beautiful glass, and is often called crystal. Crown glass contains no lead. It is composed of soda and fine sand. This kind is used for the panes of windows. Bottle glass is the coarsest of all. It is composed of kelp, or the refuse of soap-boilers, and common sand. Its green colour is owing to the presence of iron. Of these species the most fusible is flint glass, and the least fusible bottle glass. According to the experiments of Saussure, flint glass melts at the temperature of 19° Wedgewood, crown glass at 30°, and bottle glass at 47°.

Glass is often tinged of various colours by mixing with it while in fusion some one or other of the metallic oxides; and on this process, well conducted, depends the formation of pastes or factitious gems.

Blue glass is formed by means of oxide of cobalt.

Green, by the oxide of iron or of copper.

Violet, by oxide of manganese.

Red, by a mixture of the oxides of copper and iron.

Purple, by the purple oxide of gold.

White, by the oxide of arsenic and of zinc.

Yellow, by the oxide of silver and by combustible bodies.

Opticians, who employ glass for optical instruments, often complain of the many defects under which it labours. The chief of these are the following:

Streaks. These are waved lines, often visible in glass, which interrupt distinct vision. They are probably owing sometimes to want of complete fusion, which prevents the different materials from combining sufficiently; but in some cases also they may be produced by the workmen lifting up, at two different times, the glass which is to go to the formation of one vessel or instrument.

Tears. These are white specks or knots, occasioned by the vitrified clay of the furnaces, or by the presence of some foreign salt.

Bubbles. These are air-bubbles which have not been allowed to escape. They indicate want of complete fusion, either from too little alkali, or the application of too little heat.

Cords. These are asperities on the surface of the glass, in consequence of too little heat.

Blowing of glass vessels. The furnace for this (fig. 5. Plate Manufacture of Glass) has several mouths, according to the number of workmen. Each mouth consists of three holes, ABD; D is a hole through which the workman takes his metal from the melting-pot; A is the hole at which he afterwards heats his metal; and B is a small hole at which he heats the ends of his blowing-pipe and iron rods *aa*, which are supported by an iron bar across the mouth of the furnace. The furnace is built of fire-bricks, and has three domed chambers, one above another, within it; the fire is made upon a large grate in the middle of the lower one, to which the air is admitted by an arch underground; the flame goes through an opening in the dome of this chamber, and strikes against the top of the next chamber, and is thereby reverberated upon the pots, which stand upon the floor, just within the hole D; the smoke goes through the floor and roof of the next chamber, which is used as an annealing oven. This furnace is inclosed within a large building, like an inverted funnel, with a chimney at the top.

The principal implements used by the glass-blower are, a blowing-pipe, fig. 1, which is an iron pipe about two feet long, with rope-yarn wrapped round it at A, where the workman takes hold of it; two or three iron rods, fig. 2, of the same length; a pair of blunt shears, fig. 3; and several different sized ladles, shovels, pokers, &c. He has also two stools, figs. 6 and 7, to be hereafter described.

For explaining the operation, we shall describe the method of making a goblet. The workman dips the end D of his blowing-pipe, fig. 1, which is hot, through the hole D, fig. 5, into the melting-pot, which contains the glass in a state of fusion; and by turning it about, a small quantity of the glass, which is called metal, sticks to the iron: this he repeats three or four times (between each dip rolling it on an iron plate, fixed on the stool, fig. 7, to bring it into form) till he has got metal enough: he then blows at the end B of the pipe, which expands the metal into a hollow globular form; and then by swinging it round his head, it lengthens out in the shape of a bladder. The workman then sits down on the stool, fig. 6, between the two bars H and I, across which he lays the blowing-iron, and rolls it along under his left hand, following it at the same time with the shears, fig. 3, in his right hand, the blades *nn* of which embrace it, and by gently putting them in the proper place, he brings the glass into the form shewn in fig. 10; meanwhile, the boy who attends him brings a lump of metal from the furnace on the end of one of the iron rods fig. 2, which he sticks on the bottom, or part *a*, fig. 10, and by twisting the rod round, he separates the metal from the rod, and leaves it on the glass vessel; the workman then rolls the rod and vessel as before, and with his shears, as shewn in fig. 9, brings the lump of glass into the form of a stem and foot, as there described. The boy then holds the tool, fig. 4, against the bottom of the foot *b*, while it is turning, to flatten it. The boy next takes another iron rod, fig. 2, and gets a very small piece of metal on its end: this he applies to the centre of the bottom of the foot, so as to connect it to the rod; when the workman, by touching it at

the neck *d* with a wet iron, cracks the glass, so that a slight blow upon the rod with the hand will separate it at *d*, from the blowing-pipe M. The glass has by this time become too cold to work without heating again, which is done before the fire A, fig. 5; the workman then returns to the stool, fig. 6, and again rolls the rod round with his left hand as before, and with the point of one of the blades *n* of the shears opens the end *d*, fig. 8, of the glass; after which he inserts both points, and finally works it into the form of fig. 13. It is now separated from the rod N, and is carried on a shovel like a baker's peel by the boy to the annealing furnace, or oven in the upper part of the furnace, where it remains in a low red-heat for many hours, by which its former extreme brittleness is removed.

Window-glass is made in a similar manner, except that the liquid mass at the end of the tube is formed into a cylindrical shape, which being cut longitudinally by scissars or shears, is gradually bent back until it becomes a flat plate.

Large plate-glass for looking-glasses, &c. is made by suffering the mass in a state of complete fusion to flow upon a table, with iron ledges to confine the melted matter, and as it cools a metallic roller is passed over it, to reduce it to an uniform thickness.

Good glass ware is often ornamented by the glass-cutter before it is offered for sale (see fig. 12.); this is generally performed by a machine, fig. 14, wherein AA is a large wheel to be turned by a man at the winch B. The band of this wheel passes round a pulley *a* on the axle of a wheel or cutter C, and thereby turns it with a great velocity: beneath the cutter a cistern D is placed, and above it a small cask E to contain water, the cock *b* of which is so placed and adjusted as to drop very slowly on the circumference of the cutter. The glass-grinder sits down on the stool F, and after dressing the edge of the cutter with emery paste, he applies successively the parts of the glass which are to be cut, as shewn in fig. 11, and dexterously moves the glass, as the parts intended to be cut are sufficiently ground away: after this another similar cutter is applied instead of C, or the same is dressed with finer emery paste, or mixture of tripoli and other polishing powders, in order to polish the parts which have been cut; such parts as are intended to have a white appearance are left rough. The cutters *c* are formed of hard wood or soft metal, and the workman is provided with several, of different sizes and thicknesses, particularly at the edge, according to the device which is to be cut on the glass. It is by the fine edge of these cutters that letters, flowers, &c. are cut on glasses by dexterous workmen.

Glass, painting on. A few years since, Mr. Farrant obtained a patent for painting, spangling, gilding, and silvering glass, which was performed on the back of the crystal or glass, so as when finished to appear on the front; the colours prepared in oil or varnish as in other works. The parts of ornament which are gold must be first shadowed on the glass, and when dry the gold leaf must be laid on. Silver ornament is to be done in the same manner. For the spangling, leave the parts to be spangled to the last; then shadow them, and when dry varnish the parts with copal varnish, and strew the spangles

on while it is wet; when they are dry, varnish them two or three times.

The antient manner of painting in glass was very simple, and consequently very easy: it consisted in the mere arrangement of pieces of glass of different colours in some sort of symmetry, and constituted what is now called mosaic work.

In process of time they came to attempt more regular designs, and also to represent figures heightened with all their shades: yet they proceeded no farther than the contours of the figures in black with water-colours, and hatching the draperies after the same manner on glasses of the colour of the object they designed to paint. For the carnation, they used glass of a bright-red colour, and upon this they drew the principal lineaments of the face, &c. with black.

But in time, the taste for this sort of painting improving considerably, and the art being found applicable to the adorning of churches, &c. they found out means of incorporating the colours in the glass itself, by heating them in the fire to a proper degree, having first laid on the colours. The colours used in painting or staining of glass are very different from those used in painting either in water or oil colours.

For black, take scales of iron one ounce, scales of copper one ounce, jet half an ounce; reduce them to powder, and mix them. For blue, take powder of blue one pound, sal nitre half a pound; mix them, and grind them well together. For carnation, take red chalk eight ounces, iron scales and litharge of silver of each two ounces, gum arabic half an ounce; dissolve in water; grind all together for half an hour as stiff as you can; then put it in a glass and stir it well, and let it stand to settle 14 days. For green, take red-lead one pound, scales of copper one pound, and flint five pounds; divide them into three parts, and add to them as much nitre; put them into a crucible, and melt them with a strong fire; and when it is cold, powder it, and grind it to a porphyry. For gold-colour, take silver an ounce, antimony half an ounce; melt them in a crucible; then pound the mass to powder, and grind it on a copper plate; add to it yellow ochre, or brick-dust calcined again, 15 ounces, and grind them well together with water. For purple, take minium one pound, brown stone one pound, white flint five pounds; divide them into three parts, and add to them as much nitre as one of these parts; calcine, melt, and grind it as you did the green. For red, take jet four ounces, litharge of silver two ounces, red chalk one ounce; powder them fine, and mix them. For white, take jet two parts, white flint, ground on a glass very fine, one part, mix them. For yellow, take Spanish brown ten parts, leaf silver one part, antimony half a part; put all into a crucible, and calcine them well.

In the windows of antient churches, &c. there are to be seen the most beautiful and vivid colours imaginable, which far exceed any of those used by the moderns, not so much because the secret of making those colours is entirely lost, as that the moderns will not go to the charge of them, nor be at the necessary pains. Those beautiful works which were made in the glass-houses were of two kinds.

In some, the colour was diffused through

the whole substance of the glass. In others, which were the more common, the colour was only on one side, scarcely penetrating within the substance above one-third of a line; though this was more or less according to the nature of the colour, the yellow being always found to enter the deepest. These last, though not so strong and beautiful as the former, were of more advantage to the workmen, since on the same glass, though already coloured, they could shew other kind of colours where there was occasion to embroider draperies, enrich them with foliage, or represent other ornaments of gold, silver, &c.

In order to this, they made use of emery, grinding or wearing down the surface of the glass, till they were got through the colour to the clear glass. This done, they applied the proper colours on the other side of the glass. By this means, the new colours were hindered from running and mixing with the former, when they exposed the glasses to the fire, as will appear hereafter.

When, indeed, the ornaments were to appear white, the glass was only bared of its colour with emery, without tinging the place with any colour at all; and this was the manner by which they wrought their lights and heightenings on all kinds of colour.

The first thing to be done in order to paint or stain glass in the modern way, is to design and even colour the whole subject on paper. They then choose such pieces of glass as are clear, even, and smooth, and proper to receive the several parts, and proceed to distribute the design itself, or papers it is drawn on, into pieces suitable to those of the glass; always taking care that the glasses may join in the contours of the figures and the folds of the draperies, that the carnations and other finer parts may not be impaired by the lead with which the pieces are to be joined together. The distribution being made, they mark all the glasses as well as papers, that they may be known again; which done, applying every part of the design upon the glass intended for it, they copy or transfer the design upon this glass with the black colour diluted in gum water, by tracing and following all the lines and strokes as they appear through the glass with the point of a pencil.

When these strokes are well dried, which will happen in about two days, the work being only in black and white, they give a slight wash over with urine, gum arabic, and a little black, and repeat it several times, according as the shades are desired to be heightened, with this precaution, never to apply a new wash till the former is sufficiently dried.

This done, the lights and risings are given by rubbing off the colour in the places with a wooden point, or the handle of the pencil.

As to the other colours above-mentioned, they are used with gum-water, much as in painting in miniature, taking care to apply them lightly for fear of effacing the outlines of the design; or even, for the greater security, to apply them on the other side; especially yellow, which is very pernicious to the other colours, by blending with them. And here too, as in pieces of black and white, particular regard must always be had not to lay colour on colour, or lay on a new lay till such time as the former are well dried.

It may be added, that the yellow is the only colour that penetrates through the glass,

and incorporates with it by the fire; the rest, and particularly the blue, which is very difficult to use, remaining on the surface, or at least entering very little. When the painting of all the pieces is finished, they are carried to the furnace or oven, to anneal or bake the colours.

The furnace here used is small, built of brick, from 18 to 30 inches square; at six inches from the bottom is an aperture to put in the fuel, and maintain the fire. Over this aperture is a grate, made of three square bars of iron, which traverse the furnace, and divide it into two parts. Two inches above this partition is another little aperture, through which they take out pieces to examine how the coction goes forward. On the grate is placed a square earthen pan, six or seven inches deep, and five or six inches less every way than the perimeter of the furnace. On the one side is a little aperture, through which to make trials, placed directly opposite to that of the furnaces destined for the same end. In this pan are the pieces of glass to be placed in the following manner: First, the bottom of the pan is covered with three strata or layers, of quick lime pulverized; those strata being separated by two others of old broken glass, the design of which is to secure the painted glass from the too intense heat of the fire. This done, the glasses are laid horizontally on the last or uppermost layer of lime.

The first row of glass they cover over with a layer of the same powder, an inch deep; and over this they lay another range of glasses, and thus alternately till the pan is quite full, taking care that the whole heap always end with a layer of the lime-powder.

The pan being thus prepared, they cover up the furnace with tiles, on a square table of earthenware, closely luted all round, only leaving five little apertures, one at each corner, and another in the middle, to serve as chimneys. Things thus disposed, there remains nothing but to give the fire to the work. The fire for the first two hours must be very moderate, and must be increased in proportion as the coction advances, for the space of ten or twelve hours, in which time it is usually completed. At last the fire, which at first was charcoal, is to be of dry wood, so that the flame covers the whole pan, and even issues out at the chimneys.

During the last hours, they make essays, from time to time, by taking out pieces laid for the purpose through the little aperture of the furnace and pan, to see whether the yellow is perfect, and the other colours in good order. When the annealing is thought sufficient, they proceed with great haste to extinguish the fire, which otherwise would soon burn the colours, and break the glasses.

By several statutes, regulations are made for making, importing, and exporting glass, which is to be under the management of the officers of the customs and excise. See Complete Abridgement of the Excise Laws.

GLAUBER'S SALT, a cathartic or purging salt. See SODA, sulphat of.

GLAUCOPIS, in ornithology, a genus of birds of the order picæ. Bill incurvate, arched, the lower mandible shorter, and carunculate beneath at the base; nostrils depressed, half-covered with a membrane; tongue slit, and fringed at the tip; feet walkers. It inhabits New Zealand.

GLAUX, *milkwort*, a genus of the monogynia order, in the pentandria class of plants, and in the natural method ranking under the 17th order, calycanthemæ. The calyx is monophyllous; there is no corolla; the capsule is unilocular, quinquevalved, and pentaspermous. There is one species.

GLAZIER, an artificer who works in glass. The principal part of a glazier's business consists in fitting panes of glass to the sashes and window-frames of houses, pictures, &c. and in cleaning the same when required.

GLAZIER'S VICE, is an instrument for drawing lead: see Plate Miscel. fig. 102. PG, QH, are two axles running in the frame KL, ML; C, D, two wheels of iron case-hardened, $1\frac{1}{2}$ inch broad, and of the thickness of a pane of glass; these wheels are fixed to the axles, and run very near one another, their distance not exceeding one-tenth of an inch: across their edges several nicks are cut, the better to draw the lead through. E, F, are two pinions, each of twelve leaves, turning one another and going upon the ends of the axles, which are square, being kept fast there by the nuts P, Q, which are screwed fast with a key. A, B, are two cheeks of iron, case-hardened, and fixed on each side to the case with screws; these are cut with an opening near the two wheels, and set so near to the wheels as to leave a space equal to the thickness of the lead; so that between the wheels and the cheeks there is left a hole of the form represented at N, which is the shape of the lead when cut through. The frame KLML is held together by cross bars passing through the sides, and screwed on; and a cover is put over the machine to exclude the dust. The whole is screwed down fast to a bench by screw-nails LL. When the vice is used, the lead to be drawn is first cast in moulds, into pieces a foot long, with a gutter on each side. One of these pieces is taken, and an end of it sharpened with a knife; then being put into the hole between the wheels, by turning the handle I the lead is drawn through the vice, and receives the form designed.

GLAZING, the crusting over earthenware by a vitreous substance, the basis of which is commonly lead. The usual composition for glazing ware is formed of white sand 40 pounds, of red-lead 20 pounds, of pearl-ashes 20 pounds, and of common salt 12 pounds. Powder the sand by grinding it, and then add it to the other ingredients, and grind them together; after which calcine them for some time with a moderate heat, and when the mixture is cold, reduce it to powder, and when wanted for use temper it with water. The proportion of these ingredients may be occasionally varied. The ware, after being turned on the wheel and dried in the open air, is covered over with the above composition by means of a brush; and when set in the furnace, the violent heat soon reduces it to a perfect glass, covering the whole internal and external surface of the vessel. We may observe, however, that lead, being poisonous, ought to be excluded from the composition of glazings, and other fluxes substituted in its stead. A transparent glazing may be prepared without lead by calcining 40 pounds of white sand, 25 pounds of pearl-ashes, and 15 pounds of common salt, and proceeding as before: and a more perfect transparent glazing may be made of

sand 40 pounds, of wood-ashes perfectly burned 50 pounds, of pearl-ashes 10 pounds, and of common salt 12 pounds. The following receipts are taken for the most part from Kunckel, who says that they are the true glazings used at Delft and other Dutch manufactories.

Black is made of eight parts of red-lead, iron-filings three, copper-ashes three, and zaffer two measures. This when melted will make a brown-black, and if wanted blacker, add more zaffer to it.

Blue is thus prepared: Take lead-ashes or red-lead one pound; clear sand or powdered flints two pounds, common salt two pounds, white calcined tartar one pound, Venice or other glass half a pound, zaffer half a pound; mix them and melt them for several times, quenching them always in cold water. If you would have it fine and good, it will be proper to put the mixture into a glass-furnace for a day or two. Another blue glazing may be formed of one pound of tartar, a quarter of a pound of red-lead, half an ounce of zaffer, and a quarter of a pound of powdered flints, which are to be fused and managed as in the last receipt. Or, take two pounds of calcined lead and tin, add five pounds of common salt, five pounds of powdered flints, and of zaffer, tartar, and Venetian glass, each one pound. Calcine and fuse the mixture as before. Or again, take of red-lead one part, of sand three parts, and of zaffer one part. For a violet-blue glazing, take four ounces of tartar, two ounces of red-lead, five ounces of powdered flints, and half a dram of manganese.

Brown is made of red-lead and flints, of each 14 parts, and of manganese two parts fused, or of red-lead 12 parts, and manganese one part fused. A brown glazing, to be laid on a white ground, may be made of manganese two parts, and of red-lead and white glass, of each one part, twice fused.

Flesh-coloured is made of 12 parts of lead-ashes, and one of white glass.

Gold-coloured. Take of litharge three parts, of sand or calcined flint one part; pound and mix these very well together, then run them into a yellow glass with a strong fire. Pound this glass, and grind it into a subtile powder, which moisten with a well-saturated solution of silver; make it into a paste, which put into a crucible, and cover it with a cover. Give at first a gentle degree of fire; then increase it, and continue it till you have a glass, which will be green. Pound this glass again, and grind it to a fine powder; moisten this powder with some beer, so that by means of a hair-pencil you may apply it upon the vessels or any piece of earthenware. The vessels that are painted or covered over with this glazing must be first well heated, then put under a muffle; and as soon as the glass runs, you must smoke them by holding them over burning vegetables, and take out the vessels.

Kunckel gives several preparations for a gold-coloured yellow glazing. This may be produced by fusing a mixture of three parts of red-lead, two parts of antimony, and one part of saffron of Mars; by again melting the powdered mass, and repeating the operation four times, or by fusing four or five times a composition of red-lead and antimony, of each an ounce, and of scales of iron half an ounce; or by calcining and fusing together

eight parts of red-lead, six parts of flint, one part of yellow ochre, one part of antimony, and one part of white glass. A transparent gold-coloured glazing may be obtained by twice fusing red-lead and white flints, of each 12 parts, and of filings of iron one part.

Green may be prepared of eight parts of litharge or red-lead, eight parts of Venice glass, four parts of brass-dust or filings of copper; or of ten parts of litharge, twelve of flint or pebble, and one of as ustuin or copper ashes. A fine green glazing may be produced by fusing one part of the Bohemian granite, one of filings of copper, one of red-lead, and one of Venetian glass; or by fusing one part of white glass, the same quantity of red-lead, and also of filings of copper; powdering the mass, and adding one part of Bohemian granite to two parts of this powder. A fine green may be obtained by mixing and grinding together any of the yellow glazings with equal quantities of the blue glazings; and all the shades and tints of green will be had by varying the proportion of the one to the other, and by the choice of the kind of yellow and blue.

Sea-green is made of five pounds of lead-ashes, one pound of tin-ashes, three pounds of flint, three quarters of a pound of salt, half a pound of tartar, and half a pound of copper-dust.

Iron-colour is prepared of 15 parts of lead-ashes or red-lead, 14 of white sand or flints, and five of calcined copper. This mixture is to be calcined and fused.

Liver-colour is prepared of 12 parts of litharge, eight of salt, six of pebble or flint, and one of manganese.

Purple brown consists of lead-ashes 15 parts, clean sand or powdered flints 18 parts, manganese one part, and white glass 15 measures, to which some add one measure of zaffer.

Red is made of antimony three pounds, litharge or red-lead three, and rust of iron one; grind them to a fine powder. Or, take two pounds of antimony, three of red-lead, and one of calcined saffron of Mars, and proceed as before.

White. The white glazing for common ware is made of 40 pounds of clear sand, 75 pounds of litharge or lead-ashes, 26 of pot-ashes, and 10 pounds of salt; these are three times melted into a cake, quenching it each time in clear cold water. Or it may be made of 50 pounds of clean sand, 70 of lead-ashes, 30 of wood-ashes, and 12 of salt. For a fine white, take two pounds of lead and one of tin; calcine them to ashes: of this take two parts; calcined flint, white sand, or broken white glass, one part; and salt, one part; mix them well together, and melt them into a cake for use. The trouble of calcining the tin and lead may be prevented by procuring them in a proper state. A very fine white glazing may be obtained by calcining two parts of lead and one part of tin, and taking one part of this mass, and of flints and common salt of each one part, and fusing the mixture. A white glazing may be also prepared by mixing 100 pounds of masticot, 60 of red-lead, 20 of calcined tin or putty, and 10 of common salt, and calcining and powdering the mixture several times.

Yellow is prepared of red-lead three pounds, calcined antimony and tin of each

two pounds; or, according to some, of equal quantities of the three ingredients. These must be melted into a cake, then ground fine, and this operation repeated several times; or it may be made of 15 parts of lead-ore, three parts of litharge of silver, and 15 parts of sand. A fine yellow glazing may be procured by mixing five parts of red-lead, two parts of powdered brick, one part of sand, one part of the white glazings, and two parts of antimony, calcining the mixture and then fusing it. Or, take four parts of white glass, one part of antimony, three parts of red-lead, and one part of iron-scales, and fuse the mixture; or fuse 16 parts of flints, one part of iron-filings, and 24 parts of litharge. A light-yellow glazing may be produced with ten parts of red-lead, three parts of antimony, and three of glass, and two parts of calcined tin (see gold-colour above). A citron yellow is made of six parts of red-lead, seven parts of fine red brickdust, and two parts of antimony. This mixture must be calcined day and night for the space of four days, in the ash-hole of a glass-house furnace, and at last urged to fusion. See *STONE WARE*.

GLEANNING. It has been said, that by the common law and custom of England the poor are allowed to enter and glean upon another's ground after the harvest, without being guilty of trespass; and this humane provision seems borrowed from the Mosaic law. 3 Black. 212.

But it is now positively settled, by a solemn judgment of the court of common pleas, that a right to glean in the harvest-field cannot be claimed by any person at common law; neither have the poor of a parish, legally settled, such a right. 1 H. Black. Rep. 51—63.

GLEBE. Glebe land is a portion of land, meadow, or pasture, belonging to, or parcel of, the parsonage or vicarage, over and above the tithes. Godolph. Rep. 409.

Glebe lands, in the hands of the parson, shall not pay tithes to the vicar; nor being in the hands of the vicar, shall they pay tithe to the parson. Deggs, Pars. Couns. c. 2.

By stat. 28 H. VIII. c. 11, every successor on a month's warning, after induction, shall have the mansion-house and the glebe belonging thereto, not sown at the time of the predecessor's death. He that is instituted may enter into the glebe land before induction, and plead right against all strangers.

When a parson or vicar has caused any of his glebe lands to be manured and sown, at his own charge, with corn or grain, he may by will devise all the profits and corn growing upon the said glebe; and in case he dies without disposing thereof, his executors shall have the same.

GLECHOMA, *ground-ivy*, a genus of the gymnospermia order, in the didynamia class of plants, and in the natural method ranking under the 42d order, verticillata. Each pair of the antheræ come together in the form of a cross; the calyx is quinquefid. There is one species, the hederacea, or common ground-ivy, which is so well known that it requires no description. Many virtues were formerly attributed to this plant, which it is now found not to be possessed of. Some however it has. The leaves are thrown into the vat with ale, to clarify it and give it a fla-

vour. Ale thus prepared is often drunk as an-antiscorbutic. The expressed juice, mixed with a little wine, and applied morning and evening, is said to destroy specks upon horses' eyes. The plants that grow near it do not flourish. It is said to be hurtful to horses if they eat much of it. Sheep eat it; horses are not fond of it; cows, goats, and swine, refuse it.

GLEDITSIA, *triple-thorned acacia*, or *honey-locust*, a genus of the diœcia order, in the polygamia class of plants, and in the natural method ranking under the 33d order, lomentaceæ. The hermaphrodite calyx is quadrifid, the corolla tetrapetalous, the stamina six, one pistil and legumen. The male calyx is triphyllous; the corolla tripetalous, with six stamina. The female calyx is pentaphyllous; the corolla pentapetalous, one pistil and legumen.

There is one species. The triacanthos, a native of Virginia and Pennsylvania, is of an upright growth, and its trunk is guarded by thorns of three or four inches in length in a remarkable manner. These thorns have also others coming out of their sides at nearly right angles: their colour is red. The branches are smooth, and of a white colour. These are likewise armed with red thorns, that are proportionably smaller: they are of several directions, and at the ends of the branches often stand single. The young shoots of the preceding summer are perfectly smooth, of a reddish green, and retain their leaves often until the middle of November. Although there is a peculiar oddity in the nature and position of the spines, yet the leaves constitute the greatest beauty of these trees: they are doubly pinnated, and of a delightful shining green. The pinnated leaves that form the duplication do not always stand opposite by pairs on the middle rib; the pinnae of which they are composed are small and numerous; no less than 10 or 11 pair belong to each of them; and as no less than four or five pair of small leaves are arranged along the middle rib, the whole compound leaf consists often of more than 200 pinnae of this fine green colour. They sit close, and spread open in fine weather; though during bad weather they will droop, and their upper surfaces nearly join, as if in a sleeping state. The flowers are produced from the sides of the young branches in July: they are a greenish catkin, and make little show; though many are succeeded by pods that have a wonderful effect; for these are exceedingly large, more than a foot, sometimes a foot and a half in length, and two inches in breadth, and of a nut-brown colour when ripe, so that the effect, when hanging on the sides of the branches, may easily be imagined. We receive the seeds from America in the spring, which keep well in the pods, and are for the most part good. They generally arrive in February; and, as soon as possible after, they should be sown in a well-sheltered warm border of light sandy earth. If no border is to be found that is naturally so, it may be improved by applying drift sand, and making it fine. The seeds should be sown about half an inch deep, and they will for the most part come up the first spring. If the summer should prove dry, they must be constantly watered; and if shade could be afforded them in the heat of the day, they would make stronger plants by the autumn.

A careful attention to this article is peculiarly requisite; for, as the ends of the branches are often killed, if the young plant has not made some progress, it will be liable to be wholly destroyed by the winter's frost, without protection: and this renders the sowing the seeds in a warm border under a hedge in a well-sheltered place necessary; for there these shrubs will endure our winters, even when seedlings, and so will require no farther trouble; nay, though the tops should be nipped, they will shoot out again lower, and will soon overcome it. It will be proper to let them remain two years in the seed-bed before they are planted out in the nursery. The spring is the best time for the work. These trees are late in the spring before they exhibit their leaves, but keep shooting long in the autumn.

GLINUS, a genus of the pentagynia order, in the decandria class of plants, and in the natural method ranking under the 22d class, caryophyllæi. The calyx is pentaphyllous; there is no corolla; the nectarium is composed of bifid bristles; the capsule is quinqueangular, quinquelocular, quinquevalved, and polyspermous. There are three species, herbs of Arabia and the south of Europe.

GLIRES, the name given by Linnæus to the fourth order of the mammalia; the character of which is, fore-teeth cutting, two in each jaw; no tusks; feet with claws formed for running and bounding; food, bark, roots, vegetables, &c. which they gnaw. The order includes ten genera, viz. the hystrix, cavia, castor, mus, arctomys, sciurus, myoxus, dipus, lepus, and hyrax.

GLISTER, in surgery, the same with clyster.

GLOBBA, a genus of the monogynia order, in the monandria class of plants. The corolla is equal and trifid, the calyx trifid above, the capsule trilocular, with many seeds. There are four species, herbs of the East Indies.

GLOBE, in geometry, a round or spherical body, more usually called a sphere. See **SPHERE**.

GLOBE is more particularly used for an artificial sphere of metal, plaister, paper, or other matter, on whose convex surface is drawn a map or representation either of the earth or heavens, with the several circles conceived thereon.

Globes are of two kinds, terrestrial and celestial; each of very considerable use, the one in astronomy, and the other in geography, for performing many of the operations in an easy obvious manner, so as to be conceived without any knowledge of the mathematical grounds of those arts. The fundamental parts, common to both globes, are an axis, representing that of the world, and a spherical shell or cover, which makes the body of the globe, on the external surface of which the representation is drawn.

The globes commonly used are composed of plaister and paper in the following manner. A wooden axis is provided, somewhat less than the intended diameter of the globe, and into the extremes two iron wires are driven for poles: this axis is to be the beam or basis of the whole structure. On the axis are applied two spherical or rather hemispherical caps, formed on a kind of wooden mould or block. These caps consist of pasteboard or

paper, laid one lay after another on the mould, to the thickness of a crown-piece; after which, having stood to dry and enbodied, making an incision along the middle, the two caps thus parted are slipped off the mould. They remain now to be applied on the poles of the axis, as before they were on those of the mould; and to fix them in their new place, the two edges are sewed together with packthread, &c.

The rudiments of the globe thus laid, they proceed to strengthen and make it smooth and regular. In order to this, the two poles are hasped in a metalline semicircle of the size intended; and a kind of plaister made of whiting, water, and glue, heated, melted, and incorporated together, is daubed all over the paper surface. In proportion as the plaster is applied, the ball is turned round in the semicircle, the edge of which pares off whatever is superfluous, and beyond the due dimension, leaving the rest adhering in places that are short of it. After such application of plaister, the ball stands to dry; which done it is put again in the semicircle, and fresh matter applied: thus they continue alternately to apply the composition and dry it, till the ball every where accurately touches the semicircle; in which state it is perfectly smooth, regular, and complete.

The ball thus finished, it remains to paste the map or description on it. In order to this, the map is projected in several gores or gussets, all which join accurately on the spherical surface, and cover the whole ball. To direct the application of these gores, lines are drawn by a semicircle on the surface of the ball, dividing it into a number of equal parts corresponding to those of the gores, and subdividing those again answerably to the lines and divisions of the gores.

The papers thus pasted on, there remains nothing but to colour and illuminate the globe, and to varnish it, the better to resist dust, moisture, &c. The globe itself thus finished, they hang it in a brass meridian, with an hour-circle and a quadrant of altitude, and thus fit it into a wooden horizon.

GLOBES, *use of*. By the assistance of the globes a great number of curious, useful, and entertaining problems are worked, some of which we shall proceed to describe. The globe consists of several parts: as (1) the two poles, being the ends of the axis on which the globe turns, representing the diurnal motion of the earth, and the apparent diurnal motion of the heavens. (2) The brazen meridian, on which are marked the degrees from the equator to the poles. (3) The wooden horizon or frame that supports the whole globe, on which are drawn several circles, as that on which the signs of the zodiac are marked; that containing the calendar or days of the month which correspond to the several degrees of the zodiac; and that on which are delineated the 32 points of the compass. (4) The hour-circle, divided into twice 12 hours, representing the division of time for the day and the night. And, (5) a thin slip of brass, called the quadrant of altitude, useful in several problems to measure the distances and directions of the places from each other.

There are ten principal circles represented upon globes, viz. six greater and four lesser ones. The greater circles are, the brazen

meridian, already described; the equinoctial, as it is called on the celestial, and equator on the terrestrial globe; the ecliptic drawn along the middle of the zodiac; and the two colures. The lesser circles, of principal use, are the two tropics and the two polar circles. Of these circles some are fixed, and always obtain the same position; others moveable, according to the position of the observer. The fixed circles are the equator and ecliptic, with their parallels and secondaries; which are usually delineated upon the surface of the globes. The moveable circles are the horizon, with its parallels and secondaries.

The horizon is that great and broad wooden circle surrounding the globe, and dividing it into two equal parts, called the upper and lower hemispheres. It has two notches, to let the brazen meridian slip up and down, according to the different heights of the pole. On the flat side of this circle are described the twelve signs, the months of the year, the points of the compass, &c. The brazen meridian is an annulus or ring of brass, divided into degrees. It divides the globe into two equal parts, called the eastern and western hemispheres. The quadrant of altitude is a thin pliable plate of brass, answering exactly to a quadrant of the meridian. It is divided into 90°, and has a notch, nut and screw, to fix to the brazen meridian in the zenith of any place, where it turns round a pivot, and supplies the room of vertical circles. The hour-circle is a flat ring of brass, divided into 24 equal parts or hour-distances; and on the pole of the globe is fixed an index that turns round with the globe, and points out the hours upon the hour-circle. Lastly, there are generally added a compass and needle upon the pediment of the frame.

The surface of the celestial globe may be esteemed a just representation of the concave expanse of the heavens, notwithstanding its convexity; for it is easy to conceive the eye placed in the centre of the globe, and viewing the stars on its surface, supposing it made of glass, as some globes are: also that if holes were made in the centre of each star, the eye in the centre of the globe, properly placed, would view through each of the holes the very stars in the heavens represented by them.

As it would be impossible to have any distinct notion of the stars, in respect to their number, order, and distances, without arranging them in certain forms, called constellations, this the first observers of the heavens took care to do; and these, like kingdoms and countries upon the terrestrial globe, serve to distinguish the different parts of the superficies of the celestial globe. The stars, therefore, are all disposed in constellations under the forms of various animals, whose names and figures are represented on the celestial globe, which were first invented by the antient astronomers and poets, and are still retained for the better distinction of these luminaries.

PROBLEMS ON THE CELESTIAL GLOBE.

1. *To rectify the globe:* that is, to place it in such a particular situation as is necessary for the solution of many problems. Raise or elevate the pole to the latitude of the place; screw the quadrant of altitude in the zenith; set the index of the hour-circle to the upper XII, and place the globe north and south by

the compass and needle; then it is a just representation of the heavens for the given day at noon.

2. *To find the sun's place in the ecliptic.* Find the day of the month in the calendar on the horizon, and right against it is the degree of the ecliptic which the sun is in for that day.

3. *To find the sun's declination.* Rectify the globe, bring the sun's place in the ecliptic to the meridian, and that degree which it cuts in the meridian is the declination required.

4. *To find the sun's right ascension.* Bring the sun's place to the meridian, and the degree of the equinoctial cut by the meridian is the right ascension required.

5. *To find the sun's amplitude.* Bring the sun's place to the horizon, and the arch of the horizon intercepted between it and the east or west point, is the amplitude, north or south.

6. *To find the sun's amplitude for any given day and hour.* Bring the sun's place to the meridian, set the hour-index to the upper XII; then turn the globe till the index points to the given hour, where let it stand; then screwing the quadrant of altitude in the zenith, lay it over the sun's place, and the arch contained between it and the horizon will give the degrees of altitude required.

7. *To find the sun's azimuth for any hour of the day.* Every thing being done as in the last problem, the arch of the horizon contained between the north point and that where the quadrant of altitude cuts it, is the azimuth east or west as required.

8. *To find the time when the sun rises or sets.* Find the sun's place for the given day, bring it to the meridian, and set the hour-hand to XII; then turn the globe till the sun's place touches the east part of the horizon, the index will shew the hour of its rising; after that, turn the globe to the west part of the horizon, and the index will shew the time of its setting for the given day.

9. *To find the length of any given day or night.* This is easily known by taking the number of hours between the rising and setting of the sun for the length of the day; and the residue to 24, for the length of the night.

10. *To find the hour of the day, having the sun's altitude given.* Bring the sun's place to the meridian, and set the hour-hand to XII; then turn the globe in such a manner, that the sun's place may move along by the quadrant of altitude (fixed in the zenith) till it touches the degree of the given altitude, where stop it, and the index will shew on the horary circle the hour required.

11. *To find the place of the moon, or any planet, for any given day.* Take White's Ephemeris, and against the given day of the month you will find the degree and minute of the sign which the moon or planet possesses at noon, under the title of geocentric motions. The degree thus found being marked in the ecliptic on the globe by a small notch or otherwise, you may then proceed to find the declination, right ascension, latitude, longitude, altitude, azimuth, rising, southing, setting, &c. in the same manner as has been shewn for the sun.

12. *To explain the phenomena of the harvest moon.* In order to this we need only consider, that when the sun is in the begin-

ning of Aries, the full moon on that day must be in the beginning of Libra: and since, when the sun sets or moon rises on that day, those equinoctial points will be in the horizon, and the ecliptic will then be least of all inclined thereto, the part or arch which the moon describes in one day, viz. 13°, will take up about an hour and a quarter ascending above the horizon; and, therefore, so long will be the time after sun-set, the next night, before the moon will rise. But at the opposite time of the year, when the sun is in the autumnal, and the full moon in the vernal, equinox, the ecliptic will, when the sun is setting, have the greatest inclination to the horizon; and, therefore, 13° will in this case soon ascend, viz. in about a quarter of an hour; and so long after sun-set will the moon rise the next day after the full: whence, at this time of the year, there is much more moonlight than in the spring; and hence this autumnal full moon came to be called the harvest moon, the hunter's or shepherd's moon; all which may be clearly shewn on the globe.

13. *To represent the face of the starry firmament for any given hour of the night.* Rectify the globe, and turn it about till the index points to the given hour; then will all the upper hemisphere of the globe represent the visible half of the heavens, and all the stars on the globe will be in such situations as exactly correspond to those in the heavens, which may therefore be easily found, as will be shewn in the 16th problem.

14. *To find the hour when any known star will rise, or come upon the meridian.* Rectify the globe, and set the index to XII; then turn the globe till the star comes to the horizon or meridian, and the index will shew the hour required.

15. *To find at what time of the year any given star will be on the meridian at XII at night.* Bring the star to the meridian, and observe what degree of the ecliptic is on the north meridian under the horizon; then find in the calendar on the horizon the day of the year against that degree, and it will be the day required.

16. *To find any particular star.* First find its altitude in the heavens by a quadrant, and the point of the compass it bears on; then, the globe being rectified, and the index turned to the given hour, if the quadrant of altitude is fixed on the zenith, and laid towards the point of the compass on which the star was observed, the star required will be found at the same degree of altitude on the said quadrant, as it was by observation in the heavens.

PROBLEMS ON THE TERRESTRIAL GLOBE.

1. *To find the latitude of any place.* Bring the given place to the brazen meridian, and observe what degree it is under, for that is the latitude required.

2. *To rectify the globe for any given place.* Raise the pole so many degrees above the horizon as are equal to the latitude of the place; then, finding the sun's place, bring it to the meridian, and proceed as directed in problem 1. on the celestial globe.

3. *To find the longitude of a given place.* Bring the place to the brazen meridian, and observe the degree of the equator under the same, for that expresses the longitude required.

4. To find any place by the latitude and longitude given. Bring the given degree of longitude to the meridian, and under the given degree of latitude you will see the place required.

5. To find all those places which have the same latitude or longitude with those of any given place. Bring the given place to the meridian; then all those places which lie under the meridian have the same longitude; again, turn the globe round on its axis; then all those places which pass under the same degree of the meridian with any given place have the same latitude with it.

6. To find all those places where it is noon at any given hour of the day in any place. Bring the given place to the meridian, set the index to the given hour; then turn the globe till the said index points to the upper XII, and observe what places lie under the brass meridian; for to them it is noon at that time.

7. When it is noon at any one place, to find what hour it is at any other given place. Bring the first given place to the meridian, and set the index to the upper XII; then turn the globe till the other given place comes to the meridian, and the index will point to the hour required.

8. For any given hour of the day in the place where you are, to find the hour of the day in any other place. Bring the place where you are to the meridian, set the index to the given hour, then turn the globe about; and when the other place comes to the meridian, the index will shew the hour of the day there as required.

9. To find the distance between any two places in English miles. Bring one place to the meridian, over which fix the quadrant of altitude; and then laying it over the other place, count the number of degrees thereon contained between them; which number multiply by $69\frac{1}{2}$ (the number of miles in one degree), and the product is the number of English miles required.

10. To find how any one place bears from another. Bring one place to the brass meridian, and lay the quadrant of altitude over the other, and it will shew on the horizon the point of the compass on which the latter bears from the former.

11. To find those places to which the sun is vertical in the torrid zone for any given day. Find the sun's place in the ecliptic for the given time, and bring it to the meridian, and observe what degree thereof it cuts; then turn the globe about, and all those places which pass under that degree of the meridian, are those required.

12. To find what day of the year the sun will be vertical to any given place in the torrid zone. Bring the given place to the meridian, and mark the degree exactly over it; then turn the globe round, and observe the two points of the ecliptic which pass under that degree of the meridian: lastly, see on the wooden horizon on what days of the year the sun is in those points of the ecliptic; for those are the days required.

13. To find those places in the north frigid zone where the sun begins to shine constantly without setting, on any given day between the 21st of March and the 21st of June. Find the sun's place in the ecliptic for the given day, bring it to the brazen meridian, and observe the degrees of declination; then all those places which are the same number of

degrees distant from the pole are the places required to be found.

14. To find on what day the sun begins to shine constantly without setting, on any given place in the north frigid zone, and how long. Rectify the globe to the latitude of the place, and, turning it about, observe what point of the ecliptic between Aries and Cancer, and also between Cancer and Libra, coincides with the north point of the horizon; then find, by the calendar on the horizon, what days the sun will enter those degrees of the ecliptic, and they will satisfy the problem.

15. To find the place over which the sun is vertical on any given day and hour. Find the sun's place, and bring it to the meridian, and mark the degree of declination for the given hour; then find those places which have the sun in the meridian at that moment; and among them that which passes under the degree of declination is the place desired.

16. To find, for any given day and hour, those places wherein the sun is then rising and setting, or on the meridian; also those places which are enlightened, and those which are not. Find the place to which the sun is vertical at the given time, and bring the same to the meridian, and elevate the pole to the latitude of the place; then all those places which are in the western semicircle of the horizon have the sun rising, and those in the eastern semicircle see it setting; and to those under the meridian it is noon. Lastly, all places above the horizon are enlightened, and all below it are in darkness or night.

17. The day and hour of a solar or lunar eclipse being given, to find all those places in which the same will be visible. Find the place to which the sun is vertical at the given instant, and elevate the globe to the latitude of the place; then in most of those places above the horizon will the sun be visible during his eclipse; and all those places below the horizon will see the moon pass through the shadow of the earth in her eclipse.

18. The length of a degree being given, to find the number of miles in a great circle of the earth, and thence the diameter of the earth. Admit that one degree contains $69\frac{1}{2}$ English statute miles; then multiply 360 (the number of degrees in a great circle) by $69\frac{1}{2}$, and the product will be 25020, the miles which measure the circumference of the earth. If this number be divided by 3.1416, the quotient will be $7963\frac{8}{100}$ miles for the diameter of the earth.

19. The diameter of the earth being known, to find the surface in square miles, and its solidity in cubic miles. Admit the diameter to be 7964 miles; then multiply the square of the diameter by 3.1416, and the product will be 199250205 very near, which are the square miles in the surface of the earth. Again, multiply the cube of the diameter by 0.5236, and the product 264466789170 will be the number of the cubic miles in the whole globe of the earth.

20. To express the velocity of the diurnal motion of the earth. Since a place in the equator describes a circle of 25020 miles in 24 hours, it is evident, that the velocity with which it moves is at the rate of $1042\frac{1}{2}$ in one hour, or $17\frac{3}{10}$ miles per minute. The velocity in any parallel of latitude decreases in the proportion of the co-sine of the latitude to the radius. Thus for the latitude of London, $51^{\circ} 30'$, say,

| | |
|--|-----------|
| As radius | 10.000000 |
| To the co-sine of lat. $51^{\circ} 30'$ | 9.794149 |
| So is the velocity in the }
equator, $17\frac{3}{10}$ | 1.232046 |
| To the velocity of the city }
of London, $10\frac{8}{10}$ | 1.032195 |

That is, the city of London moves about the axis of the earth at the rate of $10\frac{8}{10}$ miles every minute of time.

GLOBULAR CHART, a name given to the representation of the surface, or of some part of the surface, of the terrestrial globe upon a plane, wherein the parallels of latitude are circles nearly concentric, the meridian curves bending towards the poles, and the rhomb-lines are also curves.

GLOBULAR SAILING. See SAILING.

GLOBULARIA, *globular blue daisy*, a genus of the monogynia order, in the tetrandria class of plants, and in the natural method ranking under the 48th order, aggregatæ. The common calyx is imbricated, the proper one tubulated inferior, the upper lip of the florets bipartite, the under one tripartite, the receptacle paleaceous. There are eight species, but one only is commonly to be met with in our gardens, viz. the vulgaris, or common blue daisy. It has broad thick radical leaves, three-parted at the ends, upright stalks from about six to ten or twelve inches high, with spear-shaped leaves, and the top crowned by a globular head of fine blue flowers, composed of many florets in one cup. It flowers in June, and makes a good appearance, but thrives best in a moist shady situation. It is propagated by parting the roots in September.

GLORIOSA, *superb lily*, a genus of the hexandria monogynia class of plants, the flower of which consists of six oblongo-lanceolated, undulated, and very long petals, reflex nearly to the base: the fruit is an oval pellucid capsule, containing three cells, and numerous globose seeds, disposed in a double series. There are two species, herbaceous plants of Guinea.

GLOSSOMA, a genus of the tetrandria monogynia class and order. The calyx is turbinate, four-toothed, superior; corolla four-petalled; antheras almost united with membranaceous scales at the end; stigmas four; drupe. There is one species, a shrub of Guiana.

GLOSSOPETALUM, a genus of the pentandria pentagynia class and order. The calyx is five-toothed; petals five, with a strap at the tip of each berry. There are two species, trees of Guiana.

GLOSSOPETRA, in natural history, a genus of extraneous fossils, so called from their having been supposed the tongues of serpents turned to stone, though they are really the teeth of sharks, and are found in the mouths of those fishes, wherever taken. The several sizes of teeth of the same species and the several different species of sharks, furnish us with a vast variety of these fossile teeth. Their usual colours are black, bluish, whitish, yellowish, or brown. In shape they are commonly somewhat approaching to triangular; some are simple, and others have a smaller point on each side the larger one; many of them are quite straight, but they are frequently met with crooked, and bent in all the different directions, some inwards,

some outwards, and some sideways: they are also of various sizes, the larger ones being four or five inches long, and the smaller less than a quarter of an inch. They are found with us in the strata of blue clay, and are very plentiful in the clay-pits of Richmond, and some other places; but they are no where so common as in the island of Malta.

GLOTTIS. See **ANATOMY**.

GLOVE, a covering for the hand and wrist. Gloves, with respect to commerce, are distinguished into leathern, silk, thread, cotton, worsted, &c. Leathern gloves are made of chamois, kid, lamb, doe, elk, buff, &c. To throw the glove, was a practice or ceremony very usual among our forefathers, being the challenge whereby another was defied to single combat. It is still retained at the coronation of our kings, when the king's champion casts his glove in Westminster-hall. Favyn supposes the custom to have arisen from the Eastern nations, who, in all their sales and deliveries of lands, goods, &c. used to give the purchaser their glove by way of livery or investiture. To this effect he quotes Ruth iv. 7. where the Chaldee paraphrase calls *glove* what the common version renders by *shoe*. He adds, that the rabbins interpret by *glove* that passage in the cxxviii Psalm, In Idumean extendam calceamentum meum, "Over Edom will I cast my shoe." Accordingly, among us, he who took up the glove declared thereby his acceptance of the challenge; and as a part of the ceremony, continues Favyn, took the glove off his own right hand and cast it upon the ground, to be taken up by the challenger. This had the force of a mutual engagement on each side, to meet at the time and place which should be appointed by the king, parliament, or judges. The same author asserts, that the custom which once obtained of blessing gloves in the coronation of the kings of France, was a remain of the Eastern practice of giving possession with the glove, l. xvi. p. 1017, &c. Antiently it was prohibited the judges to wear gloves on the bench; and at present, in the stables of some princes, it is said to be unsafe going in without pulling off the gloves.

GLOW-WORM. See **CICINDELA**.

GLOXINIA, a genus of the didynamia angiospermia class and order. The calyx is superior, five-leaved; corolla bell-shaped, with the border oblique; filaments with the rudiment of a fifth inserted into the receptacle. There is one species, a herb of South America.

GLUCINA, a new earth, discovered in 1798, in the mountains of Siberia. According to the experiments of Vauquelin and Klaproth, we learn that

1. To obtain glucina pure, the beryl or emerald reduced to powder, is to be fused with thrice its weight of potass. The mass is to be diluted with water, dissolved in muriatic acid, and the solution evaporated to dryness. The residuum is to be mixed with a great quantity of water, and the whole thrown on a filtre. The silica, which constitutes more than half the weight of the stone, remains behind; but the glucina and the other earths, being combined with muriatic acid, remain in solution. Precipitate them by means of carbonat of potass. Wash the precipitate, and then dissolve it in sulphuric

acid. Add to the solution sulphat of potass; evaporate it to the proper consistence, and set it by to crystallize. Alum crystals gradually form. When as many of these as possible have been obtained, pour in the liquid carbonat of ammonia in excess, then filtre, and boil the liquid for some time. A white powder gradually appears, which is glucina.

2. Glucina, thus obtained, is a soft light white powder, without either taste or smell, which has the property of adhering strongly to the tongue. It has no action on vegetable colours. It is altogether infusible by heat; neither does it harden or contract in its dimensions, as is the case with alumina. Its specific gravity is 2.967.

It is insoluble in water, but forms with a small quantity of that liquid a paste which has a certain degree of ductility.

3. It does not combine with oxygen nor any of the simple combustibles; but sulphurated hydrogen dissolves it, and forms with it a hydrosulphurat, similar to other hydrosulphurats in its properties.

4. Azote has no action on it; but muriatic acid dissolves it, and forms with it a sweet-tasted salt, called muriat of glucina.

5. Glucina is soluble in the liquid fixed alkalies, in which it agrees with alumina. It is insoluble in ammonia, but soluble in carbonat of ammonia, in which respect it agrees with yttria; but it is about five times more soluble in carbonat of ammonia than that earth.

It combines with all the acids, and forms with them sweet-tasted salts, as is the case also with yttria.

GLUE, among artificers, a tenacious viscid matter, which serves as a cement to bind or connect things together. See **GELATINE**.

GLUTA, a genus of the class and order pentandria monogynia. The calyx is bell-shaped, deciduous; petals five; filaments inserted into the tip of the column; germ sitting in an oblong column. There is one species, a tree of Java.

GLUTEUS. See **ANATOMY**.

GLUTEN. If wheat flour is kneaded into paste with a little water, it forms a tenacious, elastic, soft, ductile mass. This is to be washed cautiously, by kneading it under a small jet of water till the water no longer carries off any thing, but runs off colourless; what remains behind is called gluten. It was discovered by Beccaria, an Italian philosopher, to whom we are indebted for the first analysis of wheat flour.

1. Gluten, when thus obtained, is of a grey colour, exceedingly tenacious, ductile, and elastic, and may be extended to twenty times its original length. When very thin, it is of a whitish colour, and has a good deal of resemblance to animal tendon or membrane. In this state it adheres very tenaciously to other bodies, and has often been used to cement together broken pieces of porcelain. Its smell is peculiar. It has scarcely any taste, and does not lose its tenacity in the mouth. When exposed to the air, it assumes a brown colour, and becomes in a manner covered with a coat of oil.

When exposed to the air, it gradually dries; and when completely dry, it is pretty hard, brittle, slightly transparent, of a dark-brown colour, and has some resemblance to

glue. It breaks like a piece of glass, and the edges of the fracture resemble in smoothness those of broken glass; that is, it breaks with a vitreous fracture.

It is insoluble in water, though it imbibes and retains a certain quantity of it with great obstinacy. To this water it owes its elasticity and tenacity. When boiled in water it loses both these properties.

When kept moist, it very soon begins to decompose, and to undergo a species of fermentation. It swells, and emits air-bubbles, which Proust has ascertained to consist of hydrogen and carbonic acid gases. It emits also a very offensive odour, similar to what is emitted by putrefying animal bodies. Cadet kept gluten for a week in a damp room. Its surface became covered with byssi, the fermentation just mentioned had commenced, and the odour was distinctly acid. In 24 days, on removing the upper crust, the gluten was found converted into a kind of paste, of a greyish-white colour, not unlike bird-lime. In that state he gave it the name of fermented gluten. If the gluten is still left to itself, it gradually acquires the smell and the taste of cheese. This curious fact was first ascertained by Rouelle junior, to whom we are indebted for the most important dissertation on gluten which has yet appeared. In that state it is full of holes, and contains the very same juices which distinguish some kinds of cheese. Proust ascertained that it contains ammonia and vinegar; bodies which Vauquelin detected in cheese: and ammonia robs both equally of their smell and flavour.

When moist gluten is suddenly dried, it swells amazingly. Dry gluten, when exposed to heat, cracks, swells, melts, blackens, exhales a fetid odour, and burns precisely like feathers or horn. When distilled, there comes over water impregnated with ammonia and an empyreumatic oil; the charcoal which remains is with difficulty reduced to ashes.

2. Gluten is insoluble in water; it is equally insoluble in alcohol and in ether. But when the fermented gluten of Cadet is triturated with a little alcohol into a mucilage, and then mixed with a sufficient quantity of that liquid, a portion of it is dissolved. This solution constitutes an excellent varnish, possessed of considerable elasticity. It may be spread over paper or wood; and when dry resists other bodies as well as most varnishes. In this state too it may be employed to cement china; and triturated with paints, especially vegetable colours, it forms a very good ground. When this solution is mixed with a sufficient quantity of lime, it forms a very good lute; and bits of linen dipt in it adhere very strongly to other bodies.

All the acids dissolve it, even when very much diluted; alkalies precipitate it again, but it is deprived of its elasticity, and brought nearer to the state of extractive matter. Concentrated sulphuric acid renders it violet-coloured, and at last black; inflammable air escapes, and charcoal, water, and a portion of ammonia, are formed. When nitric acid is poured on it, and heat applied, there is a quantity of azotic gas emitted, as Berthollet discovered; and by continuing the heat, some little oxalic acid is formed, and like-

wise malic acid, while a number of yellow-coloured oily flakes make their appearance in the solution. Acetic acid acts but imperfectly, but it dissolves the fermented gluten of Cadet; and the solution may be substituted for the solution in alcohol as a varnish; but it does not answer to mix it with colours.

Alkalies dissolve gluten when they are assisted by heat. The solution is never perfectly transparent. Acids precipitate the gluten from alkalies, but it is destitute of its elasticity. Alkalies, when much concentrated, form with it a kind of soap, converting it into oil and ammonia, which last is dissipated during the trituration.

The action of the metallic oxides and their salts upon gluten has not been tried.

It has a strong affinity for the colouring matter of vegetables, and likewise for resinous bodies.

3. The properties of this substance clearly point out a resemblance between it and animal matter; and the phenomena of its fermentation and destructive distillation shew us that oxygen, hydrogen, carbon, and azote, are constituents of it. Proust has observed, that the vapour which it emits, while fermenting, blackens silver and lead, and of course contains sulphur.

4. Like all other vegetable principles, gluten is susceptible of various shades of properties, which constitute so many species. In wheat flour, it occurs in the greatest abundance, and from it we can extract it with the greatest ease. But the sagacity and industry of Rouelle and Proust have detected its presence in many other vegetable substances. Rouelle found it in the leaves of all the vegetable substances which he examined. The exactness of this opinion was called in question by Fourcroy, who treated the experiments of Rouelle with contempt; but it has been lately examined and confirmed by very decisive experiments of Proust.

When the juice of cabbage-leaves, cresses, scurvy-grass, and other similar plants, is extracted by pressure, and passed through a cloth, it still continues far from transparent. Its muddiness is owing to a fine soft silky green powder suspended in it, which subsides to the bottom so slowly as to take at least a week before it is deposited. This green powder has been distinguished by the name of the green fecula of plants. Rouelle first examined it with attention, and ascertained its properties; and the subject has been carried still farther by Proust. The slowness with which it subsides shows that its specific gravity does not differ much from that of water. When once it has fallen, it is insoluble. This substance consists chiefly of three principles: 1. A green matter to which it owes its colour, separated by digestion in alcohol, and which possesses the properties of a resin. 2. A substance which consists chiefly of woody fibres, and which is left behind when the fecula is digested in potass. 3. A species of gluten, which constitutes the greatest part of it, and to which it owes its characteristic properties.

When the juice of the plants is exposed to a heat of about 130°, the green fecula undergoes a kind of coagulation, concreting into large flakes, which subside very quickly. At this temperature, albumen is not altered

by heat. This is the method commonly taken to clarify these juices. We see from it, that the fecula was united to the water by a very small force, which the addition of heat weakened sufficiently to enable the gluten to cohere. This coagulation by heat takes place how diluted soever the juices are with water, which is by no means the case with albumen. It is thrown down also by the addition of a little alcohol, by all acids, by ammonia, by sulphurated hydrogen gas, or by throwing into the liquid crystals of carbonate of potass, magnesia, common salt, muriat of potass, nitre, sal ammoniac, &c.

When separated from water, it soon dries, and becomes elastic, and has somewhat of the appearance of horn; and in that state is scarcely softened by hot water. When treated like gluten, it gradually acquires the cheesy taste and smell. When kept under water, it very soon begins to putrefy, and exhales a gas which blackens silver and solutions of lead. This speedy putrefaction in stagnant water takes place when flax and hemp are steeped. These substances contain green fecula in their rind, and the putrefaction occasions the separation of the whole, which could not otherwise be accomplished. The water which has been allowed to remain for a whole year over green fecula, contains sulphurated hydrogen, carbonate of ammonia, and gluten seemingly held in solution by the ammonia. The stench of putrefaction still continues even after the water has been boiled.

5. The number of plants containing gluten is very considerable. Proust found it in acorns, chesnuts, horse-chesnuts, rue, barley, rye, peas, and beans; and in apples and quinces. He found it also in the leaves of cabbage, sedums, cress, hemlock, borage, saffron, &c.; in the berries of the elder, the grape, &c.; in the petals of the rose, &c. It occurs also in several roots. Proust could find none in the potatoe.

6. Gluten must be considered as one of the most useful of the vegetable principles. It constitutes an essential ingredient in wheat, and is the substance which renders flour of wheat so fit for forming bread. It seems also to constitute the essential part of yeast. Its uses as a varnish, a ground for paint, &c. pointed out by Cadet, likewise deserve attention. The gluten of wheat is said, in many cases at least, to constitute the base of the substance called birdlime; though that substance is supposed to be a preparation obtained from the bark of the elm, &c. and in that case is, according to Proust, a kind of turpentine or resin, soluble in alcohol, and not in the least resembling gluten.

GLYCONIAN VERSE, in antient poetry, consists of three feet, whereof the first is a spondee, the second a choriambus, and the last a pyrrhichius; or the first may be a spondee, and the other two dactyls.

Thus, *Mens re- | gnum bona pos- | sidet.*
or, *Mens re- | gnum bona | possidet.*

GLYCINE, knobbed-rooted liquorice-vetch, a genus of the decandria order, in the diadelphia class of plants, and in the natural method ranking under the 32d order, papilionaceæ. The calyx is bilabiate; the carina of the corolla turning back the vexillum with its point. There are 25 species, one of which is commonly cultivated in our gardens, the

frutescens, or Carolina kidney-bean tree. This has shrubby climbing stalks, twining round any support, 15 or 20 feet high, adorned with pinnated leaves of three pair of foli-les terminated by an odd one, and from the axillas clusters of large blueish-purple flowers, succeeded by long pods like those of the climbing kidney-bean. It flowers in June and July, but the seeds do not ripen in this country. It is easily propagated, either by seeds imported from America, where it is native, or by layers.

The glycine coccinea is an elegant little plant, lately introduced into our stoves, and easily propagated by seed, which it perfects in this country.

GLYCIRRHIZA, liquorice, a genus of the decandria order, in the diadelphia class of plants, and in the natural method ranking under the 32d order, papilionaceæ. The calyx is bilabiate; the upper lip tripartite, and the under one entire; the legumen ovate and compressed. There are four species. The glabra, or common liquorice, has a long, thick, creeping root, striking several feet deep into the ground; upright, firm, herbaceous stalks annually, three or four feet high, with winged leaves of four or five pair of oval lobes, terminated by an odd one; and from the axillas erect spikes of pale-blue flowers in July, succeeded by short smooth pods. The root of this is the useful part, which is replete with a sweet, balsamic, pectoral juice, much used in all compositions for coughs and disorders of the stomach. The echinata, or prickly-podded liquorice, is nearly like the common sort, only the seed-pods are prickly. Both these species are very hardy perennials; but the first is the sort commonly cultivated for use, its roots being fuller of juice and sweeter than the other. The roots are perennial; but the stalks rise in spring and decay in autumn.

Their propagation is effected by cuttings of the small roots issuing from the sides of the main ones near the surface of the earth, dividing them into lengths of six or eight inches, each having one or more good buds or eyes; and the proper season for procuring the sets for planting is any time in open weather from October till March, though from the middle of February till the middle of March is rather the most successful season for planting. An open situation is the most suitable for a plantation of these plants. Particular regard should also be had to the soil; it ought to be of a light loose composition, and three or four feet deep if possible; for the roots of the liquorice will arrive at that depth and more, and the longer the roots the more valuable they are for sale by weight.

In three years after planting, the roots of the liquorice will be fit to take up; and the proper season for this is, any time from the beginning of November till February; for it should neither be taken up before the stalks are fully decayed, nor deferred till late in spring, otherwise the roots will be apt to shrivel, and diminish in weight. In taking them up, the small side-roots are trimmed off, and the best divided into lengths for fresh sets, and the main roots are tied in bundles ready for sale.

Liquorice is almost the only sweet that quenches thirst; whence it was called by the Greeks adipson. Galen takes notice, that it was employed in this intention in hydropic

cases, to prevent the necessity of drinking. Mr. Fuller, in his *Medicina Gymnastica*, recommends this root as a very useful pectoral; an assertion warranted by experience. An extract is directed to be made from it in the shops; yet this preparation is chiefly brought from abroad, though the foreign extract is not the best.

GMELINA, a genus of the angiospermia order, in the didynamia class of plants, and in the natural method ranking under the 40th order, personatae. The calyx is nearly quadridentate; the corolla campanulate or bell-shaped; there are two bipartite and two simple antherae; the fruit is a plum with a bilocular kernel. There is one species, a tree of Malabar.

GNAPHALIUM, *cudweed, goldy locks, eternal flower, &c.* a genus of the polygamia superflua order, in the syngenesia class of plants, and in the natural method ranking under the 49th order, compositae. The receptacle is naked; the pappus feathered; the calyx imbricated, with the marginal scales roundish, parched, and coloured. There are 66 species; the most remarkable of which are: 1. The margaritaceum, or pearly-white eternal flower, has creeping, very spreading roots, crowned with broad, spear-shaped, white, hoary leaves; herbaceous, thick, woolly stalks, a foot and a half high, branching outward, with long, acute-pointed, white, woolly leaves, and terminated by a corymbose cluster of yellowish flowers, which appear in June and July, and are very ornamental. 2. The plantaginium has large woolly radical leaves, decumbent running roots, and herbaceous simple stalks, rising six or eight inches, terminated by a corymbus of white flowers in June, July, &c. 3. The stehas has a shrubby stalk, dividing into slender branches three feet long, terminate by corymbose clusters of yellow flowers, appearing in May and June. 4. The orientale has three varieties, with yellow, gold-coloured, and white silvery flowers. They have shrubby stalks, rising two or three feet high. 5. The odoratissimum, or sweet-scented eternal flower, has shrubby winged stalks, branching irregularly a yard high, with corymbose clusters of bright-yellow flowers, changing to a dark yellow. 6. The arboreum, or tree gnaphalium, has a woody stem, branching four or five feet high, narrow sessile leaves, with revolute borders, smooth on their upper side, and roundish bunches of pale-yellow flowers. The first three sorts are hardy, and will thrive in any soil or situation. The first two increase exceedingly by their roots; and the third is easily propagated by slips. The fourth, fifth, and sixth sorts are somewhat tender, and therefore should be kept in pots, to be sheltered in a greenhouse or garden-frame in winter. Others may be planted in the full ground, in a dry and warm situation; especially the oriental kind and varieties, and likewise the sweet-scented kind; for these two species will struggle tolerably through an ordinary winter, and make a pretty appearance during the summer months. All these are propagated by slips or cuttings of their shoots. The flowers of all these species are remarkable for retaining their beauty for years, if carefully gathered in a dry day, soon after they are blown.

GNAT. See **CULIX.**

GNEISS, in mineralogy, is composed essentially of felspar, quartz, and mica, forming plates which are laid on each other, and separated by thin layers of mica. It differs from granite in being shistose. Gneiss rocks are usually stratified. Like granite, it sometimes contains short and garnet. The beds of gneiss sometimes alternate with layers of granular limestone, shistose, hornblende, and porphyry. It is rich in ores, almost every metal having been found in gneiss rocks, either in veins or beds.

GNETUM, a genus of the monadelphia order, in the monœcia class of plants. The amentum of the male is a single scale; there is no corolla, and but one filament with a pair of antherae. The calyx of the female is of the same form; there is no corolla; the style with the stigma is trifid; the fruit a monospermous plum. There is one species, a herb of the East Indies.

GNIDIA, a genus of the monogynia order, in the octandria class of plants. The calyx is funnel-shaped and quadrifid, with four petals inserted into it; there is one seed somewhat resembling a berry. There are 11 species, shrubs of the Cape.

GNOMON, in dialling, the style, pin, or cock of a dial, which by its shadow shews the hour of the day. The gnomon of every dial represents the axis of the world. See **DIAL** and **DIALLING**.

GNOMON, in geometry. If in a parallelogram *ABCD* (plate Miscel. fig. 103.) the diameter *AC* be drawn; also two lines *EF*, *HI*, parallel to the sides of the parallelogram, and cutting the diameter in one and the same point *G*, so that the parallelogram is, by these parallels, divided into four parallelograms, then are the two parallelograms *DG*, *BG*, through which the diameter does not pass, called complements; those through which the diameter passes, *EH*, *FI*, are called the parallelograms about the diameter; and a gnomon consists of the two complements, and either of the parallelograms about the diameter, viz. *GD + HE + EI*, or *GD + FI + GB*.

GNOMON, in astronomy, a style erected perpendicular to the horizon, in order to find the altitude of the sun. Thus, in the right-angled triangle *ABC*, fig. 104., are given *AB* the length of the style, *BC* the length of its shadow, and the right angle *ABC*. Hence, making *CB* the radius, we have this analogy for finding the angle *ACB*, the sun's altitude, viz. *BC : AB :: radius : tangent of the angle C*. By means of a gnomon, the sun's meridian altitude, and consequently the latitude of the place, may be found more exactly than with the smaller quadrants. See **QUADRANT**.

By the same instrument the height of any object *GH* may be found; for as *DF* (fig. 105) the distance of the observer's eye from the gnomon, is to *DE*, the height of the style, so is *FH*, the distance of the observer's eye from the object, to *GH* its height.

The following example will serve to illustrate the above proposition. Pliny says, that at Rome, at the time of the equinoxes, the shadow is to the gnomon as 8 to 9; therefore as 8 : 9 :: 1 or radius : $\frac{9}{8} = 1.125$ a tangent, to which answers the angle $48^\circ 22'$, which is the height of the equator at Rome, and its complement $41^\circ 38'$ is therefore the

height of the pole, or the latitude of the place.

Riccioli remarks the following defects in the observations of the sun's height, made with the guomon by the antients, and some of the moderns, viz. that they neglected the sun's parallax, which makes his apparent altitude less, by the quantity of the parallax, than it would be if the guomon were placed at the centre of the earth: 2d, they neglected also the refraction, by which the apparent height of the sun is a little increased: and 3dly, they made the calculations from the length of the shadow, as if it were terminated by a ray coming from the centre of the sun's disc, whereas the shadow is really terminated by a ray coming from the upper edge of the sun's disc; so that, instead of the height of the sun's centre, their calculations gave the height of the upper edge of his disc: and, therefore, to the altitude of the sun found by the gnomon, the sun's parallax must be added, and from the sum must be subtracted the sun's semidiameter, and refraction, which is different at different altitudes; which being done, the correct height of the equator at Rome will be $48^\circ 4' 12''$, the complement of which, or $41^\circ 55' 46''$, is the latitude.

The preceding problem may be resolved more accurately by means of a ray of light let in through a small hole, than by a shadow, thus: make a circular perforation in a brass plate *EF* (fig. 106.) to transmit enough of the sun's rays to exhibit his image on the floor, or a stage; fix the plate parallel to the horizon in a high place, proper for observation, the height of which above the floor let be accurately measured with a plummet. Let the floor, or stage, be perfectly plane and horizontal, and coloured over with some white substance, to shew the sun more distinctly. Upon this horizontal plane draw a meridian line passing through the foot or the centre of the gnomon, *AG*, i. e. the point upon which the plummet falls from the centre of the hole; and upon this line note the extreme points *I* and *K* of the sun's image or diameter, and from each end subtract the image of half the diameter of the aperture, viz. *KH* and *LI*; then will *HL* be the image of the sun's diameter, which, when bisected in *B*, gives the point on which the rays fall from the centre of the sun.

Now having given the line *AB*, and the altitude of the gnomon *AG*, besides the right angle *A*, the angle *B*, or the apparent altitude of the sun's centre, is easily found, thus: as *AB : AG :: radius : tang. angle B*.

GNOSTICS, in church-history, christians so called, it being a name which almost all the antient heretics affected to take to express that new knowledge and extraordinary light to which they made pretensions; the word gnostic signifying a learned or enlightened person.

GOAT. See **CAPRA.**

GOAT-SUCKER. See **CAPRIMULGUS.**

GOBIUS, **Goby**, in ichthyology, a genus of fishes belonging to the order of thoracici. The generic character is, head small; eyes approximated; gill-membrane four-rayed; ventral fins united into the form of a funnel. There are eight species, of which the following are the principal.

1. *Gobius niger*. Common goby. This species grows to the length of six inches; the

body is soft, slippery, and of a slender form; the head rather large; the cheeks inflated; the teeth small, and disposed in two rows; from the head to the first dorsal fin is a small furrow; the first dorsal fin consists of six rays, the second, according to Linnaeus, of fourteen; the pectoral of sixteen or seventeen, closely set together, and the middlemost the longest; the others on each side gradually shorter; the ventral fins coalesce, and form a sort of funnel, by which these fish are said to affix themselves immoveably to the rocks, for which reason they are called by the name of rock-fish; the tail is rounded at the end; the general colour of the fish is dusky or blackish; but this, on close inspection, is owing to numerous small dusky or blackish specks, accompanied by brown or olive-coloured bars and clouds disposed on a whitish ground; the dorsal and anal fins are of a pale blue; the rays marked with minute black spots. This fish is a native of the Mediterranean and northern seas, and sometimes enters the mouths of the larger rivers, particularly in the beginning of summer, at which season it deposits its spawn on stones near the shores. It is in the number of edible fish, but is in no particular estimation.

2. *Gobius lanceolatus*. Lance-tailed goby. This species is distinguished by the peculiar form of its tail, which is large in proportion to the animal, and sharp-pointed at the tip; the body is of a lengthened shape, and nearly of equal diameter throughout; the head is oblong, and truncated in front; the jaws of equal length, and armed with sharp teeth; the gill-covers consist of two small laminae, and the opening of the gills is large; the vent is situated much nearer the head than the tail; the body is covered with scales, of which those toward the tail are much larger than those on the upper parts. This is a West Indian species: it is found in the rivers of Martinique and some other islands.

3. *Gobius caruleus*. Blue goby. Described by Cope from Commerson. A highly beautiful, though very small, species; colour fine blue, rather paler beneath; tail red, with a black border; length about a decimetre; mouth obtuse; teeth in the lower jaw sharp, and rather longer than those of the upper; eyes rather more distant than in others of the genus; body covered with small rough scales; first dorsal fin triangular, with the rays terminating in lengthened filaments; second dorsal terminated by a ray of twice the length of the rest; vent placed nearly in the middle of the body; tail rounded. Inhabits the seas about the eastern coasts of Africa, where it is used by the negroes as a bait for other fish. From the brilliancy of its colours it appears, when swimming in a calm sea, during a bright sunshine, like a small tube of sapphire, tipped with carbuncle.

4. *Gobius jazo*. Blue-finned goby. This species grows to the length of four or six inches, and is principally distinguished by the blue colour of its fins, and the streaks on the first dorsal fin; the jaws are of equal length, and armed with small sharp teeth; the lateral line runs in a straight direction along the middle of the body. It is a native of the Mediterranean and the Baltic, and commonly frequents the muddy shores, living on sea-insects, &c. It deposits its spawn on the soft mud; and though very prolific, is not observed to be very numerous, owing to the

small fry becoming the prey of other fishes; as a food it is held in little or no esteem.

GODFATHERS and GODMOTHERS, persons who at the baptism of infants lay themselves under an indispensable obligation to instruct them, and watch over their conduct. This custom is of great antiquity in the christian church, and was probably instituted to prevent children being brought up in idolatry, in case their parents died before they arrived at years of discretion. The number of godfathers and godmothers is reduced to two in the church of Rome, and three in the church of England; but formerly they had as many as they pleased.

GOLD. See **AURUM**, and **CHEMISTRY**.

GOLD-WIRE, a cylindrical ingot of silver, superficially gilt, or covered with gold at the fire, and afterwards drawn successively through a great number of little round holes, of a wiredrawing-iron, each less than the other, till it is sometimes no bigger than a hair of the head. See **WIREDRAWING**.

It may be observed, that before the wire is reduced to this excessive fineness, it is drawn through above 140 different holes, and that each time they draw it, it is rubbed afresh over with new wax, both to facilitate its passage, and to prevent the silver appearing through it.

GOLD-WIRE, *flatted*, is the former wire flatted between two rollers of polished steel, to fit it to be spun on a stick, or to be used flat, as it is without spinning, in certain stuffs, laces, embroideries, &c.

GOLD-THREAD, or *spun-gold*, is a flatted gold, wrapped or laid over a thread of silk, by twisting it with a wheel and iron bobbins.

Manner of forming gold-wire and gold-thread, both round and flat. First, an ingot of silver, of 24 pounds, is forged into a cylinder, of about an inch in diameter; then it is drawn through eight or ten holes, of a large coarse wiredrawing-iron, both to finish the roundness, and to reduce it to about three-fourths of its former diameter. This done, they file it very carefully all over to take off any filth remaining from the forge; they then cut it in the middle: and thus make two equal ingots thereof, each about 25 inches long, which they draw through several new holes, to take off any inequalities the file may have left, and to render it as smooth and equable as possible.

The ingot thus far prepared, they heat it in a charcoal fire; then taking some gold-leaves, each about four inches square, and weighing twelve grains, they join four, eight, twelve, or sixteen of these, as the wire is intended to be more or less gilt; and when they are so joined as only to form a single leaf, they rub the ingots reeking-hot with a burnisher. These leaves being thus prepared, they apply over the whole surface of the ingot, to the number of six, over each other, burnishing or rubbing them well down with the blood-stone, to close and smooth them. When gilt, the ingots are laid anew in a coal fire; and when raised to a certain degree of heat, they go over them a second time with the blood-stone, both to solder the gold more perfectly, and to finish the polishing. The gilding finished, it remains to draw the ingot into wire.

In order to this, they pass it through 20 holes of a moderate drawing-iron, by which it is brought to the thickness of the tag of a

lace: from this time the ingot loses its name, and commences gold-wire. Twenty holes more of a lesser iron leave it small enough for the least iron; the finest holes of which last, scarcely exceeding the hair of the head, finish the work.

To dispose the wire to be spun on silk, they pass it between two rollers of a little mill; these rollers are of nicely polished steel, and about three inches in diameter. They are set very close to each other, and turned by means of a handle fastened to one of them, which gives motion to the other. The gold-wire in passing between the two is rendered quite flat, but without losing any thing of it gilding, and is rendered so exceedingly thin and flexible, that it is easily spun on silk thread, by means of a hand-wheel, and so wound on a spool or bobbin.

GOLD-beating. They first melt a quantity of pure gold, and form it into an ingot: this they reduce, by forging, into a plate about the thickness of a sheet of paper; which done, they cut the plate into little pieces about an inch square, and lay them in the first or smallest mould to begin to stretch them; after they have been hammered here a while with the smallest hammer, they cut each of them into four, and put them into the second mould, to be extended further.

Upon taking them hence, they cut them again into four, and put them into the third mould, out of which they are taken, divided into four as before, and laid in the last or finishing mould, where they are beaten to the degree of thinness required.

The leaves thus finished, they take them out of the mould, and dispose them into little paper books, prepared with a little red bole for the gold to stick to: each book ordinarily contains 25 gold-leaves. There are two sizes of these books; 25 leaves of the smallest only weigh five or six grains, and the same number of the largest nine or ten grains.

It must be observed, that gold is beaten more or less, according to the kind or quality of the work it is intended for; that for the gold wire-drawers to gild their ingots with is left much thicker than that for gilding the frames of pictures, &c. See **GILDING**.

GOLD, *burnished*, that smoothed or polished with a burnisher.

GOLD, *mosaic*, that applied in pannels, on proper ground, distributed into squares, lozenges, and other compartments, part whereof is shadowed to heighten or raise the rest. See **MOSAIC**.

GOLD, *shell*, that used by the illuminers, and with which we write gold letters. It is made of the parings of leaf-gold, and even of the leaves themselves, reduced into an impalpable powder, by grinding on a marble with honey. After leaving it to infuse some time in aquafortis, they put it in shells, where it sticks. To use it, they dilute it with gum-water, or soap-water.

GOLD, *pure*, that purged by fire of all its impurities, and all alloy. The moderns frequently call it gold of 24 carats, but in reality there is no such thing as gold so very pure, and there is always wanting at least a quarter of a carat. Gold of 22 carats has one part of silver, and another of copper: that of 23 carats has half a part (that is, half a twenty-fourth) of each. See **CARACT**.

GOLD, in heraldry, is one of the metals, more usually called by the French name *or*.

GOLDEN NUMBER, in chronology, a number shewing what year of the moon's cycle any given year is. See **CYCLE**.

From what has been said under **CYCLE OF THE MOON**, it appears that the golden number will not shew the true change of the moon for more than 312 years, without being varied. It is to be observed, that the golden number is not so well adapted to the Gregorian as to the Julian calendar; the epact being more certain in the new style, to find which the golden number is of use. See **EPACT**, and **CYCLE**.

GOLDEN RULE, in arithmetic, is also called the rule of three, and the rule of proportion. See **ARITHMETIC**.

GOLDFINCH. See **FRINGILLA**.

GOLDSMITH, or, as some choose to express it, silversmith, an artist who makes vessels, utensils, and ornaments, in gold and silver.

The goldsmith's work is either performed in the mould, or beaten out with the hammer, or other engine. All works that have raised figures are cast in a mould, and afterwards polished and finished: plates or dishes of silver or gold are beaten out from thin flat plates; and tankards, and other vessels of that kind, are formed of plates soldered together, and their mouldings are beaten, not cast. The business of the goldsmith formerly required much more labour than it does at present; for they were obliged to hammer the metal from the ingot to the thinness they wanted: but the flattening-mills now in use reduce metals to the thinness that is required, at a very small expence. The goldsmith is to make his own moulds, and for that reason ought to be a good designer, and have a taste in sculpture; he also ought to know enough of metallurgy to be able to assay mixed metals, and to mix the alloy. See **ASSAYING**.

The goldsmiths in London employ several hands under them for the various articles of their trade; such are the jeweller, the snuff-box and toy-maker, the silver turner, the gilder, the burnisher, the chaser, the refiner, and the gold-beater. See **JEWELLER**, &c.

Goldsmiths are superior tradesmen; their wares must be assayed by the wardens of the company of this name in London, and marked: and gold is to be of a certain touch. No goldsmith may take above one shilling the ounce of gold, besides what he has for the fashioning, more than the buyer may be allowed for it at the king's exchange; and here any false metal shall be seized and forfeited to the king. The cities of York, Exeter, Bristol, &c. are places appointed for the assaying wrought plate of goldsmiths; also a duty is granted on silver plate of sixpence an ounce, &c. Plate made by goldsmiths shall be of a particular fineness, on pain of forfeiting 10*l*. and if any parcel of plate sent to the assayers is discovered to be of a coarser alloy than the respective standards, it may be broken, and defaced; and the fees for assaying are particularly limited.

GOMPHIA, a genus of the decandria monogynia class and order. The calyx is five-leaved; the corolla five-petalled; berries two; (1 to 5) in a large receptacle. Seed solitary. There are three species, trees of the East and West Indies.

GOMPHRENA, *globe amaranth*, a genus of the digynia order, in the pentandria class of plants, and in the natural method ranking under the 54th order, *miscellanæ*. The calyx is coloured; the exterior one triphyllous, or diphyllous, with two carinated convenient leaflets; the nectarium cylindrical, with ten teeth; the capsule monospermous. There are nine species, but only one of them is commonly cultivated in our gardens, viz. the *globosa*, or globe amaranth. It has an upright stalk branching all round, two or three feet high, with oval, lanceolate, and opposite leaves; and every branch and side-shoot terminated by a close globular head of flowers, composed of numerous very small starry florets, closely covered with dry scaly calices placed imbricatum, persistent, and beautifully coloured purple, white, red, or striped and variegated. The florets themselves are so small, and closely covered with the scaly calices, that they scarcely appear. The numerous closely placed scaly coverings being of a dry firm consistence, coloured and glittering, collected into a compact round head, about the size of an ordinary cherry, make a fine appearance. They are annual plants, natives of India, and require artificial heat to raise and forward them to a proper growth, so that they may flower in perfection, and produce ripe seed. They flower from June to November; and if the flowers are gathered when at full growth, and placed out of the sun, they will retain their beauty several months.

GONARCHA, in antiquity, a dial delineated on several surfaces, or planes, some horizontal, others erect, oblique, &c.

GONATOCARPUS, a genus of the tetrandria monogynia class and order. The corolla is four-cleft, drupe eight-cornered, one-seeded. There is one species, an annual of Nogsaki.

GONDOLA, a flat boat, very long and narrow, chiefly used at Venice to row on the canals. The word is Italian, gondola. Du Cange derives it from the vulgar Greek *κονιέλας*, "a bark," or "little ship;" Lancelot deduces it from *γόνδον*, a term in Athenæus for a sort of vase. The middle-sized gondolas are upwards of thirty feet long and four broad; they always terminate at each end in a very sharp point, which is raised perpendicularly to the full height of a man. The address of the Venetian gondoleers, in passing along their narrow canals, is very remarkable: there are usually two to each gondola, and they row by pushing before them. The fore man rests his oar on the left side of the gondola: the hind man is placed on the stern, that he may see the head over the tilt or covering of the gondola, and rest his oar, which is very long, on the right side of the gondola. Gondola is also the name of a passage-boat of six or eight oars, used in other parts of the coast of Italy.

GONDOLA-SHELL, in natural history. See **DOLIUM**.

GONORRHEA. See **SURGERY**.

GONIOMETRY, a method of measuring angles, so called by M. de Lagny, who gave several papers, on this method, in the *Memoirs of the Royal Academy*. M. de Lagny's method of goniometry consists in measuring the angles with a pair of compasses, and that

without any scale whatever, except an undivided semicircle. Thus, having any angle drawn upon paper, to be measured, produce one of the sides of the angle backwards behind the angular point; then with a pair of fine compasses describe a pretty large semicircle from the angular point as a centre, cutting the sides of the proposed angle, which will intercept a part of the semicircle. Take then this intercepted part very exactly between the points of the compasses, and turn them successively over upon the arc of the semicircle, to find how often it is contained in it, after which there is commonly some remainder: then take this remainder in the compasses, and in like manner find how often it is contained in the last of the integral parts of the first arc, with again some remainder: find in like manner how often this last remainder is contained in the former; and so on continually, till the remainder become too small to be taken and applied as a measure. By this means he obtains a series of quotients, or fractional parts, one of another, which being properly reduced into one fraction, give the ratio of the first arc to the semicircle, or of the proposed angle to two right angles, or 180 degrees, and consequently that angle itself in degrees and minutes.

Thus suppose the angle BAC (plate Misc. fig. 107.) be proposed to be measured. Produce BA out towards f; and from the centre A describe the semicircle *abcf*, in which *ab* is the measure of the proposed angle. Take *ab* in the compasses, and apply it four times on the semicircle, as at *b, c, d, and e*; then take the remainder *fe*, and apply it back upon *ed*, which is but once, viz. at *g*; again take the remainder *gd*, and apply it five times on *ge*, as at *h, i, k, l, and m*; lastly, take the remainder *me*, and it is contained just two times in *ml*. Hence the series of quotients is 4, 1, 5, 2; consequently the fourth or last arc *em* is $\frac{1}{2}$ the third *ml* or *gd*, and therefore the

3d arc *gd* is $\frac{1}{5\frac{1}{2}}$, or $\frac{2}{11}$ of the 2d arc *ef*; and

therefore, again this 2d arc *ef* is $\frac{1}{1\frac{2}{3}}$, or $\frac{3}{5}$ of

the 1st arc *ab*; and consequently this 1st arc *ab* is $\frac{1}{4\frac{1}{3}}$, or $\frac{3}{13}$ of the whole semicircle *af*. But

$\frac{3}{13}$ of 180° are 37 $\frac{1}{2}$ degrees, or 37° 8' 34" $\frac{2}{3}$, which therefore is the measure of the angle sought: When the operation is nicely performed, this angle may be within two or three minutes of the truth; though M. de Lagny pretends to measure much nearer than that.

GONIUM, a genus of vermes, of the order infusoria. Worm very simple, flat, angular, invisible to the naked eye. There are five species. The pectoral, quadrangular, pellucid, with 16 spherical molucles, found in pure water; molecules oval, nearly equal in size, set in a quadrangular membrane, like diamonds in a ring, the lower ones a little larger than the rest. See Adams on the Microscope.

GOOD BEHAVIOUR: surety for the good behaviour is the bail or pledge for any person that he shall do or perform such a thing, as surety for the peace is the acknowledging a recognizance or bond to the king, taken by a competent judge of record, for keeping the king's peace. Dalt. c. 116.

A binding to the good behaviour is not by way of punishment; but it is to shew, that when a man has broken the good behaviour, he is not to be trusted. 12 Mod. 566.

Justices of peace may chastise rioters, bar- rators, and other offenders, and also imprison and punish them according to law, and by discretion and good advisement; and also bind persons of evil fame to the good beha- viour, &c. 34 Ed. III. c. 1.

This statute being penned in such general words, seems in a great measure to have left it to the discretion of justices of the peace, to determine what persons should be bound to their good behaviour; and consequently seems to empower them, not only to bind over those who seem to be notoriously trouble- some, and likely to break the peace, as eves- droppers, &c. but also those who are publicly scandalous, or contemners of justice, &c. as haunters of bawdy-houses, or keepers of lewd women in their own houses; common drunk- ards, or those who sleep in the day and go abroad in the night, or such as keep suspi- cious company, or such as are generally sus- pected as robbers; or such as speak contemp- tuous words of superior magistrates, as justices of peace, mayors, &c. not being in the actual execution of their office, or of inferior officers of justice, as constables, &c. being in the ac- tual execution of their office; but it seems that rash, quarrelsome, or unmannerly words, spoken by one private person to another, unless they directly tend to a breach of the peace, are not sufficient cause to bind a man to his good behaviour. 1 Haw. 153.

GOODENIA, a genus of the pentandria monogynia class and order. The corolla is five-cleft; anthers linear; stigma cup-shaped, ciliated; caps. two-celled, two-valved. Seeds many, imbricated. There are nine species, shrubs of South Wales.

GOOSE. See ANAS.

GOOSEBERRY, grossularia. See RIBES.

GOOSE-EMBER. See MARGUS.

GOOSE-NECK, in a ship, a piece of iron fixed on the end of the tiller, to which the laniard of the whip-staff, or the wheel-rope comes, for steering the ship.

GOOSE-WING, in the sea-language. When a ship sails before, or with, a quarter-wind on a fresh gale, to make the more haste, they launch out a boom, and sail on the lee-side; and a sail so fitted, is called a goose-wing.

GORDIUS, the hair-worm, a genus of in- sects belonging to the class of vermes intes- tina. There are several species: 1. The aqua- ticus, or water hair-worm, is 10 or 12 inches in length, and of about the thickness of a horse-hair; its skin is smooth, and somewhat glossy, without furrows; its colour pale-yel- lowish white all over, except the head and tail, which are black and glossy. The body is rounded, and very slender in proportion to its length; the mouth is small, and placed horizontally; the jaws are both of the same length, and obtuse at their extremities. This species is common in our fresh waters, more especially in clay, through which it passes as a fish does through the water, and is the author of many springs. It is a variety of this worm that in Guinea, and in some other of the hot countries, gets into the flesh of the natives, and occasions great mischief; with us, though frequent enough in water where people bathe, it never attempts this. 2. The argillaceous, or clay hair-worm, is only a variation of the

preceding one in colour, being yellowish at the extremities. It chiefly inhabits the clay; Linnaeus calls that its proper element, from its being generally dug out of it. 3. The medinensis, or muscular hair-worm, is all over of a pale-yellowish colour. It is a native of both Indies; frequent in the morning dew, whence it enters the naked feet of the slaves, and occasions a disease much known in those countries, and to which children are very liable; it creates the most troublesome itch- ings, and too often excites a fever and inflam- mation. It particularly attacks the muscles of the arms and legs, whence it may be drawn out by means of a piece of silk or thread tied round the head; but the greatest caution is necessary in this simple operation, lest the animal, by being strained too much, should break; for if any part remains under the skin, it quickly grows with redoubled vigour, and becomes a cruel, and sometimes fatal enemy to the poor slaves in particular. Baths with infusions of bitter plants, and all vermifuges, destroy it. 4. The marinus, or sea hair-worm, is filiform, twisted spirally and lying flat, about half an inch in length; of a whitish colour, smooth, and scarcely di- minishing at the head. It is as great a tor- mentor of herrings, bleaks, and various other fish, as the gordius medinensis is of man. The fish, when infested with these animals, rise to the surface, and tumble about as if in great agony.

GORDONIA, a genus of the polyandria order, in the monadelphia class of plants. The calyx is simple; the style five-cornered, with the stigma quinquefid; the capsule quin- quelocular; the seeds two-fold, with a leafy wing. There are three species. The lasian- thus is a tall and very straight tree, with a regular pyramidal head. Its leaves are shaped like those of the common bay, but serrated. It begins to blossom in May, and continues bringing forth its flowers the greatest part of the summer. The flowers are fixed to foot- stalks, four or five inches long; are monope- talous, divided into five segments, encom- passing a tuft of stamina headed with yellow apices; these flowers, in November, are suc- ceeded by a conic capsula, having a divided calyx. The capsula, when ripe, opens and divides into five sections, disclosing many small half-winged seeds. This tree retains its leaves all the year, and grows only in wet places, and usually in water. The wood is somewhat soft; yet Mr. Catesby mentions his having seen some beautiful tables made of it. It grows in Carolina, but not in any of the more northern colonies.

GORGONIA, in natural history, a genus of zoophytes, which formerly were called ceratophytos, and are known in English by the names of sea-fans, sea-feathers, and sea- whips. Linnaeus and Dr. Pallas consider them as of a mixed nature in their growth, between animals and vegetables: but Mr. Ellis shows them to be true animals of the polype kind, growing up in a branched form resembling a shrub, and in no part vegetable. They differ from the fresh-water polype in many of the qualities, and particularly in producing from their own substance a hard and solid support, serving many of the pur- poses of the bone in other animals. This is formed by a concreting juice, thrown out from a peculiar set of longitudinal parallel tubes, running along the internal surface of

the fleshy part: in the coats of these tubes are a number of small orifices, through which the osseous liquor exudes, and concreting, forms the layers of that hard part of the an- nular circles, which some, judging from the consistence rather than the texture, have er- roneously denominated wood. The surface of the gorgonia is composed of a kind of scales, so well adapted to each other, as to serve for defence from external injuries; and the flesh, or, as some have called it, the bark or cortex, consists of proper muscles and ten- dons for extending the opening of their cells; for sending forth from thence their polype suckers in search of food, and for drawing them in suddenly, and contracting the sphinc- ter muscles of these starry cells, in order to secure these tender parts from danger; and also of proper secretory ducts, to furnish and deposit the osseous matter that forms the stem and branches as well as the base of the bone. Mr. Ellis affirms, that there are ova- ries in these animals, and thinks it very pro- bable that many of them are viviparous. See CORALLINES, and ZOOPHYTES.

GORE, in heraldry, one of the abatements, which, according to Guillim, denotes a cow- ard. It is a figure consisting of two arch lines drawn one from the sinister chief, and the other from the sinister base, both meet- ing in an acute angle in the middle of the fess point.

GORE, in law, signifies a narrow slip of ground.

GOREING, in the sea-language, sloping. A sail is cut goreing, when it is cut sloping by degrees, and is broader at the clew than at the earing, as all topsails and top-gallant sails are.

GORGE, in fortification, the entrance of the platform of any work. See FORTIFI- CATION.

In all the outworks, the gorge is the inter- val betwixt the wings on the side of the great ditch, as the gorge of a ravelin, half-moon, &c. These, it is to be observed, are all destitute of parapets; because if there were any, the besiegers, having taken possession of the work, might use it to defend themselves from the shot of the place, which is the rea- son that they are only fortified with pali- sadoes, to prevent a surprise.

The gorge of a bastion is nothing but the prolongation of the curtains from their angle with the flanks, to the centre of the bastion where they meet. When the bastion is flat, the gorge is a right line, which termi- nates the distance between the two flanks.

GORGED, in heraldry, the bearing of a crown, coronet, or the like, about the neck of a lion, a swan, &c. and in that case it is said, the lion or cygnet is gorged with a ducal coronet, &c.

GORTERIA, a genus of the class and order syngenesia polygamia frustranea class and order. The calyx is intricate; corolla of the ray ligulate; down, woolly; recep- tacle, naked. There are 13 species, mostly shrubby plants of the Cape.

GOSHAWK. See FALCO.

GOSSAMER is the name of a fine filmy substance, like cobweb, which is seen to float in the air in clear days in autumn, and is more observable in stubble-fields, and upon furze and other low bushes. This is prob- ably formed by the flying-spider, which, in

traversing the air for food, shoots out these threads from its anus, which are borne down by the dew, &c.

GOSSYPIMUM, or cotton; a genus of the polyandria order, in the monadelphia class of plants, and in the natural method ranking under the 37th order, columniferae. The calyx is double, the exterior one trifold; the capsule quadrilocular; the seeds wrapt in cotton-wool. There are six species, all of them natives of warm climates. 1. The herbaceous, or common herbaceous cotton, has an herbaceous smooth stalk two feet high, branching upwards; five-lobed smooth leaves; and yellow flowers from the ends of the branches, succeeded by roundish capsules full of seed and cotton. 2. The hirsutum, or hairy American cotton, has hairy stalks branching laterally two or three feet high; palmated, three and five-lobed hairy leaves; and yellow flowers, succeeded by large oval pods furnished with seeds and cotton. 3. The barbadense, or Barbadoes shrubby cotton, has a shrubby stalk branching four or five feet high, three-lobed smooth leaves, glandulous underneath; and yellow flowers succeeded by oval pods, containing seeds and cotton. 4. The arboreum, or tree cotton, has an upright woody perennial stalk, branching six or eight feet high; palmated, four or five-lobed smooth leaves, and yellow flowers, succeeded by large pods filled with seeds and cotton. The first three species are annual, but the fourth is perennial both in root and stalk. In warm countries these plants are cultivated in great quantities in the fields for the sake of the cotton they produce; but the first species is most generally cultivated. The pods are sometimes as large as middling-sized apples, closely filled with the cotton surrounding the seed. When these plants are raised in this country, they must be continually kept in a warm stove, where they will produce seeds and cotton. They are propagated by seeds.

The American islands produce cotton shrubs of various sizes, which rise and grow up without any culture, especially in low and marshy grounds. Their produce is of a pale red, some paler than others, but so short that it cannot be spun. None of this is brought to Europe, though it might be usefully employed in making hats. The little that is picked up serves to make mattresses and pillows.

The cotton shrub that supplies our manufactures requires a dry and stony soil, and thrives best in grounds that have already been tilled. Not but the plant appears more flourishing in fresh lands than in those which are exhausted; but while it produces more wood, it bears less fruit. A western exposure is fittest for it. The culture of it begins in March and April, and continues during the first spring-rains. Holes are made at seven or eight feet distance from each other, and a few seeds thrown in. When they are grown to the height of five or six inches, all the stems are pulled up, except two or three of the strongest. These are cropped twice before the end of August. This precaution is the more necessary, as the wood bears no fruit till after the second pruning; and if the shrub was suffered to grow more than four feet high, the crop would not be the greater, nor the fruit so easily gathered. The same method is pursued for three

years; for so long the shrub may continue, if it cannot conveniently be renewed oftener with the prospect of an advantage that will compensate the trouble. This useful plant will not thrive if great attention is not paid to pluck up the weeds that grow about it. Frequent rains will promote its growth, but they must not be incessant. Dry weather is particularly necessary in the months of March and April, which is the time of gathering the cotton, to prevent it from being discoloured and spotted. When it is all gathered in, the seeds must be picked out from the wool with which they are naturally mixed. This is done by means of a cotton-mill, which is an engine composed of two rods of hard wood, about 18 feet long, 18 lines in circumference, and fluted two lines deep. They are confined at both ends, so as to leave no more distance between them than is necessary for the seed to slip through. At one end is a kind of little millstone, which, being put in motion with the foot, turns the rods in contrary directions. They separate the cotton, and throw out the seed contained in it.

GOUANIA, a genus of the monoecia order, in the polygamia class of plants. The calyx of the hermaphrodite is quinquefid; there is no corolla; there are five antherae covered with an elastic calyptra or hood; the style trifold; the fruit, inferior to the receptacle of the flower, divisible into three seeds. The male is like the hermaphrodite, but wanting stigma and germen. There is one species, a shrubby plant of St Domingo.

GOUGE, an instrument or tool used by divers artificers; being a sort of round hollow chisel, for cutting holes, channels, grooves, &c. either in wood or stone.

GOURD. See **CUCURBITA**.

GOUT. See **MEDICINE**.

GRACE, *act of*, an act of parliament for a general and free pardon, and for setting at liberty insolvent debtors.

GRACE, *days of*, in commerce. See **BILLS OF EXCHANGE**.

GRACULA, the grackle, in ornithology, a genus belonging to the order of picæ. The bill is convex, cultrated, and bare at the point; the tongue is not cloven, but is fleshy and sharp; it has three toes before and one behind. 1. The religiosa, lesser grackle, or Indian stare, is about the size of a blackbird; the bill an inch and a half long, and of an orange colour. The general colour of the plumage is black, glossed with violet, purple, and green, in different reflections of light; on the quills is a bar of white; the feathers and legs are an orange-yellow, and the claws of a pale brown. This species, which is found in several parts of the East Indies, in the Isle of Hainan, and almost every isle beyond the Ganges, is remarkable for whistling, singing, and talking well, much better than any of the parrot genus, and in particular very distinct. Its food is of the vegetable kind. Those kept in this climate are observed to be very fond of cherries and grapes; if cherries are offered to one, and it does not immediately get them, it cries and whines like a young child, till it has obtained its desire. It is a very tame and familiar bird. 2. The barita, or boat-tailed grackle, is about the size of a cuckoo. The bill is sharp, black, and an inch and a half in length; the general colour of the plumage is black, with

a gloss of purple, especially on the upper parts; the legs and claws are black, the latter hooked. There is a singularity in the folding up of the tail-feathers, which, instead of forming a plain surface at top, sink into a hollow like a deep gutter. It always carries its tail expanded when on the ground, folding it up in the above singular manner only when perched or flying. It inhabits Jamaica; and it feeds on maize, beetles, and other insects, as well as on the fruit of the banana. It is likewise common in North America, keeping company with the flocks of the maize-thieves, and red-winged oriole. These breed in the swamps, and migrate in September, after which none are seen. 3. The quiscula, purple jackdaw, or Barbadoes blackbird, is about the size of a blackbird: the male bird is black, but most beautifully and richly glossed with purple, especially on the head and neck. The female is wholly of a brown colour, deepest on the wings and tail. This species inhabits Carolina, Mexico, and other parts of North America, also Jamaica. These birds for the most part feed on maize, whence the name of maize-thieves has been given them; but this is not their only food, for they are known also to feed on many other things. In spring, soon after the maize-seed is put into the ground, they scratch it up again; and as soon as the leaf comes out, they take it up with their bills, root and all; but when it is ripe they do still more damage, for at that time they come in troops of thousands, and are so bold, that if disturbed in one part of the field they only go to another. In New Jersey and Pennsylvania three pence per dozen was once given for the dead birds, and by means of the premium they were nearly extirpated in 1750: when the persecution of them was abated on account of the great increase of worms which had taken place in the meadows, and which in the preceding year had left so little hay in New England as to occasion an importation from other parts. The grakles were therefore again tolerated, as it was observed that they fed on these worms till the maize was ripe. These birds build in trees. They are said to pass the winter in swamps which are quite overgrown with wood, thence only appearing in mild weather; and after the maize is got in, are content to feed on other things, as the aquatic tare-grass, and if pressed by hunger, buck-wheat and oats, &c.: they are said also to destroy that pernicious insect the bruchus pisi. Their note is pretty and agreeable, but their flesh is not good to eat. 4. The cristatella, or Chinese starling, is a little bigger than a blackbird. The bill is yellow or orange, and the general colour of the plumage blackish with a tinge of blue; the legs are of a dull yellow. These birds, which are said to talk and whistle very well, are common in China, where they are very much esteemed, and the figures of them are seen frequently in Chinese paintings. Their food is rice, insects, worms, and such-like. They are seldom brought to England alive, requiring the greatest care in the passage. There are eight other species of gracula.

GRADUATION, in mathematics, the act of dividing any thing into degrees, or equal parts.

GRAFTING, or *grafting*, in gardening, is the insertion of a scion into a stock or stem raised for the purpose, and is necessary to

the ensuring of good fruit; i.e. to have the same (or at least with little difference) produced on the new tree, as that of the old one whence the graft was taken: it is sometimes performed on the branches of trees, and may be on the roots, a piece being raised out of the ground for the purpose.

If the seeds of fruit were left to grow up to trees without grafting, they would produce a different kind from that they came from; by chance a better, but most commonly a worse. The varieties of fruit we have, were obviously obtained from seedling stocks, without grafting.

Grafting is like planting upon a plant, for though there is a union of the parts, there is in fact little other communication than a root has with the ground. The scion, or bud, draws nourishment from the stock, but no other than is properly adapted to its own peculiar vessels, and which it alters so as to become exclusively its own.

The art of grafting is a very curious discovery, and though it requires some ingenuity to perform it, a few trials may make it familiar, and it will prove an agreeable source of amusement and satisfaction. By being able to graft, young trees may be always at hand for replacing old, or unsuccessful ones; and the pleasure of obliging a friend from our stock in this way, is peculiarly gratifying.

Skill in this ingenious art is clearly best obtained by seeing the work performed; and at first trial, to have an adept at the elbow, would be a great advantage. There are few gardeners (even by profession), however, that practise this work, owing to the great number of nurserymen ready to supply trees. But though they raise fine trees, much disappointment has often happened in dealing with them (particularly in the sort); which might be avoided, by a man's being able to raise good trees for himself. Directions precisely descriptive of the business of grafting, are therefore here attempted, and if once understood, trials should be made without minding the discouragement of a few failures; for practice will make perfect.

Proper stocks being ready, and scions or buds procured, there will be wanting a good sharp narrow-bladed penknife, and a sharp smooth-edged pruning-knife, with some well-wrought loam or clay, and some good new bass, or strong yarn. The clay should be made up as mortar, mixed with short hair, or fine chopt hay, with a little cow-dung, and prepared a day or two beforehand; or if longer the better, being beaten up afresh with a little water every day.

The first thing to be done is, to cut off the head of the stock at the proper height, and in a fair part of the bark, making a smooth flat top; if the stock is too strong for the knife, and a saw is used, it must be smoothed with the knife after. The most proper size for stocks, is from half an inch to an inch diameter: a little more or less, however, may do. When a stock is too little, the scion is apt to overgrow it, and when too big, the scion does not so well, or so soon, cover the stock, as might be wished; yet stocks of any size can be used by one mode of grafting or other.

Dwarf trees are to be grafted within six inches of the ground, and standards as high as the stock will well bear, considering whether they are to be half or full standards; the

former at about three or four feet, the latter at five or six. But trees designed for standards, may be grafted or inoculated at a lower height, the graft being trained to the desired length, by keeping it to a single stem.

The scions should be healthy and strong (not however of a soft, sappy, luxuriant growth), and taken from the outsides of fruitful trees, where the juices of the wood have been properly digested by sun and air; they should be taken (if it may be) from trees just in their prime, or at full bearing, and not before. Let them be cut two or three weeks sooner than wanted, and if kept longer they may not hurt, for they had better be cut a little too soon than too late, at full length, without any side shoots.

Let the scions of pears, plums, and cherries, be cut from the middle to the end of January, and at farthest not beyond the middle of February; the season must, however, somewhat govern. Keep them all over in dry mould, close under a south wall, or some shelter, covering them with straw in wet or severe weather. Some preserve them in a cool room, where they will do without mould, but it would be better to set them up on end in a garden-pot, half their length with mould or sand, nearly dry.

Scions cut early are prevented from getting too forward in bud: for if the buds begin to start, and look white, they seldom take. By having them as long as they may be kept before used, the sap of the stock gets in forwardness; for it must first begin to stir, and so be ready to push itself quickly into the scion (now somewhat exhausted), to form an union with it.

The middle of scions is fittest for the purpose; but do not cut off the tops till they are brought out to graft, for they keep best in length. If scions are to be transported to any distance, let their ends be stuck two or three inches in clay, and so matted round in a bundle; or, if wrapped round with a fine hay-rope, and smeared over with cow-dung, clay, or a strong earth, they will not soon wither.

Some gardeners say, scions should be only of the last year's growth, and others, that the wood of the year before is best; but it is so far a matter of indifference that they will take much older, though, perhaps, not so certainly. As a medium, if a little of the former year's wood is cut with a scion of the last, and this older wood used for the part grafted, it will be found to answer, in covering the stock sooner; though it must be acknowledged, that all new wood is the common practice of those who raise trees for sale; which circumstance is ordinarily a presumptive proof of right. If wood, however, of a year's growth is not strong enough, then, at least, some of the old wood ought to be cut with it; and the bigger the stock is, the more this practice commends itself, as the barks will be somewhat more equal in thickness.

Proceeding to graft, take off a little of the lower end of the scion first, and then cut it in length, so as to have three or four eyes to appear above the claying; two eyes will be sufficient for a standard, but four are better for a dwarf that is to be trained. In cutting scions into lengths, let the top eye be just in

front, or just behind, but rather the former. Use not (except upon necessity), the upper part of a scion, as the wood is too raw for the purpose, and will be shrivelled; yet strong scions (properly inserted) seldom miss through drought; indeed they will take sooner than if quite fresh cut and full of sap.

The time for grafting is usually from mid-February to mid-March; but in a forward season sooner, and in a backward one sometimes later.

Cleft-grafting has been the most common method of propagation, and though it is not the neatest, yet it is a certain and easy way to young practitioners. The stocks for this mode of grafting should be strong, about three quarters of an inch diameter, or more; but it may be used with very young stocks, having scions of like thickness.

Cut off the head as before directed, so as to have (on the sunny side) a smooth part in the stock, where the scion is to be placed, and cutting a part of the stock off slopewise, opposite to this place, leave the top or the crown of the stock, about half an inch wide.

Then cleave the stock with a strong knife, or thin sharp chisel, about two inches deep, as near the middle as possible, so as not to divide the pith, and if any roughness appears in the slit, smooth it off with a penknife; but something of the wedge kind must be put into the slit to keep it open to receive the scion, leaving proper room to put it in. Cut the scion on each side to the form of a wedge at bottom, an inch or more long, making that side which is to be placed inwards in the stock, thinner by about one-third. Put the scion in, so that its bark and that of the stock may be level; and consequently that the two barks may unite and run into each other; for on this one principle depends the whole art of grafting. If the bark of the stock is thick, let the bark of the scion sink in a trifle, as the current of sap that unites them, runs betwixt the bark and wood. The scion being placed, take the wedge out that kept the stock open; yet if the stock is so strong as to pinch the scion too hard, ease it by a little bit of dry wood to be left in the cleft; so, however, as not to loosen the graft, which must be held firmly: or if the stock is very strong, the wedge of the scion may be nearly of equal thickness, inside and out, which eases the barked part.

The graft must be nicely whipped round with wet bass pulled tight, and the whole clayed over to an inch above and half an inch below, smoothing it off taper, with a trowel or knife dipped in water. And as this is done with a view to keep out wet, sun, and air, if the clay falls off or cracks, it must be immediately repaired, till the season comes to take off the bandage, which is about Midsummer, or rather sooner; yet at this time some clay should be still kept on the top, to secure the cleft from wet, and so continued till the cleft is grown up.

If it is desired to put in two scions, to form a tree for the wall, or espalier, there should be two clefts parallel to one another, one on each side the pith. Some put in two scions, merely in case one should miss; but it is not advisable. It need hardly be observed, that in this case the crown must be left whole.

Whip-grafting has the advantage of cleft-grafting in neatness, and not requiring the

stocks to be so old by a year or two, as very small ones will do in this way; for the stock is directly covered by the scion, and it takes with certainty if properly performed. Scions suitable to proper stocks cannot however always be had. Stock and scion are to be both of a size; or nearly so is better, the stock having the advantage in bigness; for thus it is not so likely to be overgrown, as it happens when the scion is of a more free nature. When the stock is overgrown by the scion, it will give it some opportunity to thicken, by slitting the bark through downwards, in two or three places. This circumstance is not, however, material in dwarf trees.

Having cut the head of the stock off, and the scion to its proper length, slope the lower end of the scion about an inch and a half, and to a point; then cut the stock to answer it (the cut of the stock, however, may be a trifle wider and longer) bark against bark, and tie them together exactly to their place, and clay it. But for the greater certainty of keeping a scion to the part, cut it so as to leave a small shoulder at the top of the slope, and the stock so as to leave a narrow bit of its crown to answer it, and to hold it.

There is a sort of whip-grafting that has been denominated slicing, or packing, which differs only from that just described, in this: that the stock is of any size; and this is performed by cutting the scion to a face, as before, and then taking off a slice from the (beheaded) stock, choosing a gibbous part of it so as exactly to correspond with the cut surface of the scion, taking care to fit them so that the scion may stand erect (or nearly) when clapped to. Shouldering is commonly practised also in this way.

Grafting in the bark, or *crown-grafting*, is perhaps as good a way as any, both for ease of operation and certainty of success; but it will hardly suit any other fruit than apples or pears, as other scions will be past use (most likely) before the bark of the stocks will peel, as the time for this business is towards the end of March, or beginning of April.

The head being cut off, make a straight slit down and through the bark from the top, at the place destined for the graft, which should be rather southerly or westerly. This score down the bark should be nearly as long as the slope cut of the scion, which may be one and a half or two inches. Loosen the bark a little at the top of the score, and then with some smooth instrument of dry hard wood, ivory, bone, or silver, rather than iron or steel, open the bark sufficiently to receive the scion, by pushing the instrument down a trifle below the bottom of the slit. This instrument should be thin, tapered and rounded towards the point, to suit the shape of the scion's face; one side of it flat, and the other a little convex, the flat side being applied to the wood of the stock; let it be rather narrower than the scion, that it may not loosen the bark too wide.

Cut a bit of the bark of the scion smooth off at the bottom that it may not turn up in pushing down. It will be proper to cut the scion with a small shoulder, to rest upon the stock. And because when the scion is in, it will bear the bark up hollow from the stock, score the bark on each side the scion, so that it may fall close to the stock, and to

the edges of the scion. Bind and clay neatly. In this way of grafting there is a sort of agreement between the scion and stock necessary; the scion not being too big, or the stock too small, to prevent a proper bedding. If more than one scion is not put in, the stock on the opposite side to the scion should be sloped up about two inches in length, to half its thickness.

This way of grafting is used most properly with strong stocks; and sometimes is applied to large branches, and even trunks of old trees, to change the sorts or renew the wood. In proportion to the largeness of which, from two to five or six scions are put in, and sometimes of different sorts; and if the stock is large, the more the better, as it heals over the sooner, and as they insure the life of the stock, by receiving and carrying off the sap; in which respect a single branch of the head of an old stock may be left on, for the sap to pass off by when it begins to stir.

Side-grafting is done in the bark, much like inoculation, a scion being inserted instead of a bud; but remember, there must be a fluent sap first, *i. e.* the bark must part readily from the wood, before this mode of grafting is attempted. The head of the stock is not to be cut off, only thinned a little if it is large, and the side shoots taken away. The bark of the stock, where the insertion of the scion is to be, must be cut through in the form of the letter T, as wide and as long as is sufficient to receive the scion, cut as before, with a slope face of at least an inch long, taking advantage, (if it may be) of a part of the stock that is a little gibbous. Let the bark of the stock be neatly raised to receive it, but yet no more than necessary; a little bit of the bark may be sliced off the part that is over the cross cut, to receive the scion the better.

Approach-grafting, or *inarching*, is performed in April or May, when the stock we would graft, and the tree we would propagate, grow so near together, as to be conveniently in contact, and the nearer the graft and the stock are of a size the better. This mode of propagation is esteemed the surest of all; and in truth, some things cannot be so well propagated any other way. It is a method that is, or can be, seldom used for common fruit-trees; but if any one wishes to try the experiment, the stock or stocks must be planted at least a year before, first making the soil good, as it may need it, being so near another tree, for it of course must be close.

Plants in pots or tubs being easily brought together, are frequently propagated this way; so that inarching is used much in green-houses and hot-houses for various things, as oranges, lemons, pomegranates, jasmines, and vines sometimes; oranges and lemons thus treated in May will be united by August.

The method of inarching is, bend the best-situated young branch of the tree or shrub to be propagated, to the stock to be grafted, and having determined on the part at which most conveniently to fix the shoot, cut the bark of that part of the shoot off, with nearly half the wood (not to touch the pith) to the length of about three inches for a strong branch, or less for a weaker. Then cut exactly so much of the bark and branch of the stock off, as will receive the cut part of the

branch or shoot, so as to bring bark and bark in contact in every part; and if the contrivance of lipping is used, it will secure them better together. Bind and clay, and if in open ground, fix a stake to tie the work so that the wind may have no power over it; a tie also to a neat stick may be proper for those inarched in pots, &c.

Budding, or *inoculation*, though here last mentioned, is the most considerable mode of propagation. Apricots, peaches, and nectarines, are always propagated this way, and plums and cherries may be. Pears are sometimes budded, and apples have been, but the success is uncertain. Not only fruit, but forest, and ornamental trees and shrubs are inoculated. The branches also of trees as well as stems are sometimes budded, which is best done on two-years wood, though it may be on both younger and older.

Inoculation begins as soon as good shoots with good eyes, of the present year can be had, so that the season may be reckoned from mid-June to mid-August; but about old Midsummer, or rather after, is the usual and best time for the work; it should be done in a morning or evening (the latter rather best), except the day is cloudy, when any part of it will do.

Apricots being first ready, the budding season begins with them. The stocks to be used are those of the plum (raised from stones or suckers) when half an inch thick, a little under or over, and the operation is to take place from four to eight inches from the ground.

Peaches and nectarines are propagated on the same sort of stocks; but if the plum stock is first budded with an apricot (very low), and when of proper size budded with a peach, and especially a nectarine, the advantage is reckoned that it takes best so; and comes to a better bearing, producing an improved fruit, and particularly the red Roman nectarine. Apricots may be expected to be less luxuriant by double-budding, in which case the first bud should be of the Brussels sort.

Plums and cherries may be inoculated on sucker stocks of any kind; yet, if a free is required, (as for standards), stocks raised from stones are best; *i. e.* plums on plums, and cherries on cherries, though they will take upon each other.

Pears, if for standards, should be inoculated on pear stocks, and on those raised from seed, rather than suckers; but if for dwarfs, quince stocks may be best used, to keep the trees from growing off too fast; and so getting soon too big for their allotted space; white-thorn stocks are sometimes used with the same view, but the fruit gets stony. Stocks for budding dwarfs should be three years old; but for standards four or more.

Though the longer inoculation is deferred, the riper the shoots will be for furnishing buds; yet there is this advantage in beginning as early as may be, that if the budding appears not to have taken, the work may be done again before the season is out. Or, to ensure success, two buds may be inserted in the same stock (but not in a direction under one another), and if both fail this year, the stocks may do again the next, as the heads in grafting by inoculation are not to be cut off till the spring following, because the inserted buds do not push off till then.

Let the scions to procure buds for inoculation, be taken only from the outside branches of healthy and fruitful trees. If early budding is attempted, it will be proper to cut off some spare shoot (not fit for the purpose) to try first whether the bark will yet readily part from the wood.

The season being right, and the scions at hand, have a sharp narrow-bladed knife, and neat tough wet bass. Keep the buds, as much as may be, from sun and wind: they must not be taken from the upper part of the scions, as the bark and buds there are too raw. If scions or buds are brought from any distance, they should be conveyed in damp moss or grass, and never kept above a day and night, but the sooner they are used the better.

Before the buds are prepared, get the stock ready to receive them, by taking off lateral shoots, leaving an uncut single stem. At the part fixed on for the inoculation (which should be smooth, and rather on the north side) cut the bark through to the wood in form thus, T, the cross and the down slit being of the length necessary to take in the bud, which may be cut with from one to two inches of bark; putting the point of a knife (or some instrument rather not of iron or steel) in to the top of the down cut of the stock, raise the bark all the way to the bottom, so that it will just receive the bud easily. There are knives made on purpose for budding, with flat ivory hafts.

To procure proper buds, put your knife in (suppose) about three-fourths of an inch above the eye, and with a slope downwards cut the scion half through, then do it at the same distance below the eye, and sloping it upwards cut up the middle of the wood, till the knife meets the upper incision, so the eye, or bud, will be directly in the middle.

The next step is, to separate the wood from the bark, which is to be done thus: with your nail, or the point of a knife, loosen the bark at the top, and strip it from the wood; or rather with a swan or large goose quill, made in the form of an apple-scoop (having a regular smooth edge) push it down between the bark and wood, pressing it against the wood.

Examine the inside of the bark, and if there is a cavity just behind the eye or bud, it is good for nothing, and another must be procured; for the cavity shews, that the root of the bud is with the wood, instead of being with the bark.

The leaf that grows by the eye is to be cut down to near its footstalk, so as to leave only a little bit of it to hold the bud by, while inserting it in the stock.

See that the bark of the stock is loosened a proper length and breadth, and if, when the bud is put in, it should prove a little too long, cut the spare part off; so that the top of the bud being squared, falls in straight with the cross cut of the stock. Thus fixed, bind it moderately tight in its place with the wet bass, beginning at the bottom, and passing by the bud, go on till the top, or rather above it. Care must be taken that the bud is not hurt, and it is to be left only just starting out between the bass.

If the buds have taken, it will be seen in about three weeks or a month, by their appearing fresh and plump. As often as any

shoots appear below the budding, cut them off, and also some of the shoots above, if there are many of them: for it is not proper that an inoculated stock should have a large head. In a month loosen the bandage, by taking it off, and putting it on gently again for another month.

In March, cut the head of the stock off with a keen knife, close behind the budding, in a sloping direction; some leave three or four inches of the stock above the bud till the following spring, and it will serve to tie the new shoot to, in order to keep it to a proper erect direction. Suffer no shoots from the stock, but rub the buds off as soon as they appear. It may be of use to shade inoculated buds a few days by a leaf, or a bit of paper.

GRAIN, a small weight, the twentieth part of a scruple in apothecaries' weight, and the twenty-fourth of a pennyweight troy. A grain-weight of gold bullion is worth about two-pence, and that of silver but half a farthing.

GRAIN also denotes the component particles of stones and metals, the veins of wood, &c. Hence cross-grained, or against the grain, is contrary to the fibres of wood, &c.

GRAINING-BOARD, among curriers, an instrument called also a pummel, used to give a grain to their leather.

GRAMMAR, the art of speaking and writing any language with propriety. It is usually divided into four parts, orthography, etymology, syntax, and prosody.

GRALLÆ, in ornithology, is an order of birds, in the Linnean system, which have a beak a little cylindric, rather blunt, and bare of feathers at the base. The tongue is entire and fleshy, pointed at the end, and beset with bristles. The legs are without feathers, above the knees. This order includes 20 genera, viz. the phanicopterus, platalea, palamedea, mycteria, tantalus, ardea, coriara, recurvirostra, scolopax, tringa, fulica, parra, vaginalis, psophia, cancruma, rallus, scopus, glareola, hæmatopus, and charadrius.

GRANADIER, a soldier armed with a sword, a firelock, a bayonet, and a pouch full of hand-granadoes. They wear high caps, are generally the tallest and briskest fellows, and are always the first upon all attacks. Every battalion of foot has generally a company of grenadiers belonging to it, or else four or five grenadiers belong to each company of the battalion; which, on occasion, are drawn out, and form a company of themselves. These always take the right of the battalion.

GRANADO, a hollow ball or shell, of iron or other metal, about two inches and a half in diameter; which being filled with fine powder, is set on fire by means of a small fusee fastened to the touch-hole, made of the same composition as that of a bomb; as soon as the fire enters the shell, it bursts into many pieces, much to the damage of all that stand near.

GRANARY. See **HUSBANDRY**.

GRANATITE, a stone found in Galicia in Spain, Brittany in France, and at St. Gothard. It is always crystallised in a very peculiar form; two six-sided prisms intersect each other, either at right angles or obliquely. Hence the name cross-stone, by which it was

known in France and Spain. Mr. Haüy has proved, in a very ingenious manner, that the primitive form of the granatite is a rectangular prism, whose bases are rhombs, with angles of $129\frac{1}{2}^\circ$ and $50\frac{1}{2}^\circ$; and that the height of the prism is to the greater diagonal of a rhomb as 1 to 6; and that its integrant molecules are triangular prisms, similar to what would be obtained by cutting the primitive crystal in two, by a plane passing vertically through the shorter diagonal of the rhomboidal base. From this structure he has demonstrated the law of the formation of the cruciform varieties. The colour of granatite is greyish or reddish brown. Specific gravity 3.2861. Usually opaque. Glassy or greasy. Infusible before the blowpipe. Two specimens, analysed by Vauquelin, gave the following constituents:

| |
|--------------------------|
| From Brittany, |
| 44.00 alumina |
| 33.00 silica |
| 13.00 oxide of iron |
| 3.84 lime |
| 1.00 oxide of manganese. |

94.84

| |
|----------------------|
| From St. Gothard, |
| 47.06 alumina |
| 30.59 silica |
| 15.30 oxide of iron. |
| 3.00 lime. |

95.95

GRAND DAYS, are those days in the several terms, which are solemnly kept in the inns of the court of chancery, viz. Candlemas-day, Ascension-day, St. John the Baptist, and All Saints'-day.

GRAND JURY, is the jury which find bills of indictment before justices of peace and gaol-delivery, or of oyer and terminer, &c. against any offenders that may be tried for the fact. See **JURY**.

GRANITE, a genus of stones of the order of petrae, belonging to the class of saxa. The principal constituent parts of this stone are felspar or rhombic quartz, mica, and quartz. These ingredients constitute the hardest sort of granite, and that most antiently known. That into which schoerl enters is more subject to decomposition. They never have any particular texture or regular form, but consist of enormous shapeless masses extremely hard. In the finer granites the quartz is transparent; in others generally white or grey, violet, or brown. The felspar is generally the most copious ingredient, and of a white, yellow, red, black, or brown colour. The mica is also grey, brown, yellow, green, red, violet, or black; and commonly the least copious. The schoerl is generally black, and abounds in the granites that contain it. Hence the colour of the granites depends principally on that of the spar or schoerl. The red granites consist commonly of white quartz, red felspar, and grey mica; the grey ones of white quartz grey or violet felspar, and black mica. The black granites commonly contain schoerl instead of felspar; and the green usually contain green quartz.

On exposing granite to the flame of a blowpipe, the component ingredients sepa-

rate from one another. Mr. Gerhard having melted some in a crucible, found the felspar run into a transparent glass; below it the mica lay in form of a black slag, the quartz remaining unaltered. It melted somewhat better when all the three were powdered and mixed together; though even then the quartz was still discernible by a magnifying-glass. Hence we may explain the reason why grains of a white colour are sometimes found in volcanic lavas. The mixture of mica prevents the siliceous quartz from splitting or cracking; and hence its infusibility and use in furnace-building.

Granites are seldom slated or laminated. In those which are of a close texture, the quartz and schorl predominate. They take a good polish; for which reason the Egyptians formerly, and Italians still work them into large pieces of ornamental architecture, for which they are extremely fit, as not being liable to decay in the air. Farber, in his Letters from Italy, mentions a kind of stone named granitone, composed of felspar and mica: a substance of this kind, which moulders in the air, is found in Finland; which is said to contain nitre, and sometimes common salt. In that country it is called rapakiri. Wallerius describes 18 species of granites, besides many others akin to this genus. Those particularly in use are,

1. The hard white granite, with black spots, commonly called moor-stone. This is a very valuable kind, consisting of a beautiful congeries of very variously constructed and differently coloured particles, not diffused among or running into one another, but each pure and distinct, though firmly adhering to whichever of the others it comes in contact with, and forming a very firm mass. It is much used in London for the steps of public buildings, and on other occasions where great strength and hardness are required.

2. The hard red granite variegated with black and white, and common in Egypt and Arabia.

3. The pale-whitish granite, variegated with black and yellow. This is sometimes found in strata, but more frequently in loose nodules, and is used for paving the streets.

Some of these kinds of stones are found in almost every country, and in many places they are found of immense size. The largest mass of this kind in the known world, lying as an unconnected stone, is found near the Cape of Good Hope in Africa, and of which we have the following description in the Philosoph. Transact. vol. 68, given by Mr. Anderson, in a letter to sir John Pringle: "The stone is so remarkable, that it is called by the people here, the tower of Babel, and by some the pearl diamond. It either takes the last name from a place near which it is situated, or it gives name to the tract of cultivated land called the Pearl. It lies upon the top of a ridge of low hills, beyond a large plain, at the distance of about thirty miles from the Cape Town; beyond which, at a little distance, is a range of hills of a much greater height. It is of an oblong shape, and lies north and south. The south end is highest: the east and west sides are steep and high; but the top is rounded, and slopes away gradually to the north end, so that you can ascend it that way, and enjoy a most ex-

tensive prospect of the whole country. I could not precisely determine its circumference, but it took us about half an hour to walk round it; and by making every allowance for the rugged way, and stopping a little, I think the most moderate computation must make it exceed half a mile. The same difficulty occurred with respect to knowing its height; but I think that at the south end it is nearly equal to half its length; or, were I to compare it to an object you are acquainted with, I should say it equalled the dome of St. Paul's church." He adds,

"I am uncertain whether it ought to be considered as the top of the hill, or a detached stone, because there is no positive proof of either, unless we were to dig about its base." A part of this stone being examined by sir William Hamilton, he determined it to be a granite, and of the same nature with the tops of some of the Alps; and supposes both of them to have been elevated by volcanic explosions.

GRANITELLO, a genus of stones of the order of petre, belonging to the class of saxa. There are two species,

1. That composed of distinct particles, found in several of the mountainous parts of Sweden. In some of these there is a predominance of quartzose particles, in others of micaceous; in which last case the stone is slaty, and easily split.

2. Granitello composed of convoluted particles. This is met with of different colours, as whitish-grey, greenish, and reddish. Both these kinds of stone are used in building furnaces, on account of the powerful resistance they make to the fire; but the latter is preferable to the other, on account of its containing a little of a refractory clayish substance. It is likewise of great use in mills, where the fellow is a coarse sandstone.

GRANT, in law, a conveyance in writing of such things as cannot pass or be conveyed by word only; such are rents, reversions, services, advowsons in gross, tithes, &c.

The person making such a conveyance is called the grantor, and he to whom the grant is made the grantee.

A grant has usually the words *give and grant*, &c. which in a deed of what lies in grant, will amount either to a gift, grant, feoffment, or release, &c. and accordingly may be pleaded: though to every good grant it is requisite that there be a grantor, or person able to give; a grantee, capable of the thing granted; something granted, as grantable; that it be done in the manner the law requires; and that there be an agreement to, and an acceptance of, the grant by him to whom made, &c.

When persons non sanæ memoriæ make grants, they may be good as to themselves, though voidable by their heirs, &c. and notwithstanding infants and feme-coverts are prohibited by law to be grantors, yet they may be grantees: however an infant, when at his full age, may disagree to his grant, and the husband to that made to his wife. All grants are expounded according to the substance of the deed in a reasonable sense, and agreeable to the intent of the parties. In case a person grants a rent-charge out of land, and he has then nothing in the same, admitting he afterwards purchases the land, nevertheless the grant is void. And the law does not al-

low of grants of titles only, or imperfect interest, or of things that are merely future. Likewise grants may be void on account of uncertainty, impossibility, being against the law, &c.

GRANT of the king is good for himself and his successors, though they are not named therein: but the king may not grant away an estate-tail in the crown.

A grant tending to a monopoly cannot be made by the king, to the detriment of the interest and liberty of the subject; neither can the king make a grant non obstante any statute, made or to be made; for if he does, any subsequent statute prohibiting what is granted will be a revocation of the grant: yet there may be a non obstante to a former grant made by the king, where he has been deceived in such grant, as where it contains more than what was intended to be granted, or there is any deceit in the consideration, &c. by which the first grant becomes void.

GRANULATION. See CHEMISTRY.

GRAPE. See VITIS.

GRAPE-SHOT, in artillery, is a combination of small shot, put into a thick canvas bag, and corded strongly together, so as to form a kind of cylinder, whose diameter is equal to that of the ball adapted to the cannon. The number of shot in a grape varies according to the service, or size of the guns: in sea-service nine is always the number; but by land it is increased to any number or size, from an ounce and a quarter in weight to three or four pounds. In the sea-service the bottoms and pins are made of iron, whereas those used by land are of wood.

GRAPHIC, gold ore. See TELLURIUM.

GRAPHITES, in mineralogy, a mineral consisting principally of carbon with a little iron, and generally a little silica or alumina; when pure it burns with a reddish flame, emitting beautiful sparks, and a smell of sulphur, and leaving a little residuum. Its colour is dark iron-grey, or brownish black; when cut, blueish grey. Opaque: structure slaty. Texture fine-grained. Brittle. Specific gravity from 1.987 to 2.089; after being soaked in water 2.15; after being heated 2.3. Feels somewhat greasy, stains the fingers, and marks strongly. In modern chemistry it is denominated carburet of iron; and one of the species is plumbago; the use of which, when manufactured into pencils, is known to every one. When pure it consists of,

90 carbon
10 iron
—
100.

GRAPHOMETER, a mathematical instrument, otherwise called a semicircle, the use of which is to observe any angle, whose vertex is at the centre of the instrument in any plane (though it is most commonly horizontal, or nearly so), and to find how many degrees it contains.

The graphometer is a graduated semicircle ABC, made of wood, brass, or the like, and so fixed on a fulcrum GH, by means of a brass ball and socket, that it easily turns about, and retains any situation. It has two sights fixed on its diameter AC, and at the centre there are commonly a magnetical needle and compass in a box. There is likewise

a moveable ruler or index, ED, with two sights P, P; which turns round the centre, and retains any situation given it. See Plate Miscel. fig. 108.

To measure by this instrument any angle ACB (fig. 109), in any plane, and comprehended between the right lines AC and BC, drawn from two points A and B, to the place of station C. Let the graphometer be placed at C, supported by its fulcrum; and let the immoveable sights on the diameter of the instrument DE, be directed towards the point A; and likewise while the instrument remains immoveable, let the sights of the ruler FG, which is moveable about the centre C, be directed to the point B. Now it is evident that the moveable ruler cuts off an arch DG, which is the measure of the angle ACB, sought. Moreover, by the same method, the inclination of DE, or FG, may be observed with the meridian line, which is pointed out by the magnetic needle inclosed in the box, and moveable about the centre of the instrument.

GRAPNELS, a sort of anchors with four flocks, serving for boats to ride by.

There is also a kind called fire and chain-grapnels, made with four-barbed claws instead of flocks, and used to catch hold of the enemies' rigging, or any other part, in order for boarding them. See Plate Miscel. fig. 110.

GRASS. See BOTANY. For the culture of the different sorts of grass, see HUSBANDRY.

GRASSHOPPER, in zoology. See GRYLUS.

GRATINGS, in a ship, a kind of lattice-work formed of ledges and battens, the square holes of which being three or four inches wide, are for the current footing of men over hatchways, to give air below, and vent for the smoke in an engagement.

GRATIOLA, *hedge-hyssop*, a genus of the monogynia order, in the diandria class of plants. The corolla is irregular; there are two barren stamina; the capsule is bilocular; the calyx has seven leaves, with the two exterior ones patulous. There are 12 species; the most remarkable of which is the officinalis, or common hedge-hyssop. This grows naturally in the Alps and other mountainous parts of Europe. It has a thick, fleshy, fibrous, creeping root, which propagates very much, when planted in a proper soil and situation. From this arise several upright square stalks, with narrow spear-shaped leaves, placed opposite. The flowers are produced on the side of the stalks at each joint; they are shaped like those of the fox-glove, but are small, and of a pale-yellowish colour. This herb has an emetic and purgative virtue; to answer which intentions it was formerly used by the common people in England, but was never much prescribed by the physicians, and at last fell totally into disuse. Of late, however, it has been the subject of a dissertation by Dr. James Kostrzewski, of Warsaw, in Poland, who gives some remarkable accounts of its effects in mania and obstinate venereal cases. It was given in powder, or in extract, to the quantity of half a drachm of the first, and a whole drachm of the second, at each dose.

GRAVE, in music, is applied to a sound which is of a low or deep tone.

GRAVEL, in natural history and gardening, a congeries of pebbles, which, mixed with a stiff loam, makes lasting and elegant walks; an ornament peculiar to our gardens, and which gives them the advantage over those of all other nations.

GRAVEL. See MEDICINE.

GRAVIMETER, the name given by M. Guyton to an instrument for measuring specific gravities: he adopts this name rather than either areometer or hydrometer, because these latter terms are grounded upon the supposition that a fluid is always the thing weighed; whereas, with regard to solids, the liquid is the known term of comparison to which the unknown weight is referred.

Guyton's gravimeter is executed in glass, and is of a cylindric form, being that which requires the smallest quantity of fluid, and is on that account preferable, except so far as it is necessary to deviate for the security of a vertical position. It carries two basins; one of them superior, at the extremity of a thin stem, towards the middle of which the fixed point of immersion is marked. The other, or lower basin, terminates in a point; it contains the balls, and is attached to the cylinder by two branches. The moveable suspension by means of a hook has the inconvenience of shortening the lever which is to secure the vertical position.

The cylinder is 22 millimetres (0.71 inch) in diameter; and 21 centimetres (6.85 inches) in length. It carries in the upper basin an additional constant weight of five grammes (115 grains). These dimensions might be increased so as to render it capable of receiving a much more considerable weight; but this is unnecessary. M. Guyton has added a piece which he calls the plongeur, because in fact it is placed in the lower basin when used, and is consequently entirely immersed in the fluid. It is a bulb of glass loaded with a sufficient quantity of mercury, in order that its total weight may be equal to the constant additional weight, added to the weight of the volume of water displaced by this piece. It will be readily understood that the weight being determined at the same temperature at which the instrument was originally adjusted, it will sink to the same mark on the stem, whether it is loaded with a constant additional weight in the upper basin, or whether the effect of this weight be produced by the additional piece in the lower dish. From this explanation there will be no difficulty in seeing how this instrument may be adapted to every case in practice.

It may be used, 1. for solids. The only condition will be, that the absolute weight of the body to be examined shall be rather less than the constant additional weight, which in this instrument is five grammes, or 115 grains.

2. For liquids of less specific gravity than water the instrument, without the additional weight above-mentioned, weighs about two decagrammes (459 grains) in the dimensions before laid down. It would be easy to limit its weight to the utmost accuracy. We have therefore the range of one-fifth of buoyancy, and consequently the means of ascertaining all the intermediate densities from water to the most highly rectified spirit of wine, which

is known to bear in this respect the ratio of eight to ten with regard to water.

3. When liquids of greater specific gravity than water are to be tried, the constant weight being applied below, by means of the additional piece, which weighs about six grammes (138 grains), the instrument can receive in the upper basin more than four times the usual additional weight, without losing the equilibrium of its vertical position. In this state it is capable of shewing the specific gravity of the most concentrated acids.

4. It possesses another property, namely, that it may be used as a balance to determine the absolute weight of such bodies as do not exceed its additional load.

5. Lastly, the purity of the water being known, it will indicate the degrees of rarefaction and condensation in proportion to its own bulk.

This instrument may be readily constructed by any workman in glass. The additional piece for the lower basin will require some attention to make it perfectly agree with the constant upper weight, as to the immersion of the instrument. But this object may, by careful adjustment, be ascertained with the utmost certainty and accuracy. The bulb of glass is for this purpose drawn out to a fine point; a sufficient quantity of mercury is then introduced to sink it, and the aperture closed with a little piece of wax. The bulb being then placed in the lower basin of the instrument, the upper basin is to be loaded until the mark on the stem becomes accurately coincident with the surface of the water. The sum of the weights added above is precisely equal to that of the quantity of mercury necessary to be added to that in the glass bulb; which done, nothing more is needed than to seal the point by fusion, taking care not to change its bulk.

The whole is rendered portable by means of a case in which all the delicate parts are secured from pressure, and the heavier parts supported in such a manner as to resist the excess of motion they are capable of acquiring by virtue of their mass. This last circumstance is frequently overlooked by such workmen as are employed in the package of instruments; whence it necessarily follows, that some strain or fracture must be produced when matters of very unequal density are exposed to receive a common impulse.

To find the specific gravity of any solid by the gravimeter, observe this rule: "From the weight in the upper dish, when the instrument is properly immersed in the unknown fluid, take the weight which is placed with the body in the same scale at the like adjustment. The remainder is the absolute weight of the solid. Multiply this by the specific gravity of the fluid, and reserve the product. From the additional weight when the body is placed in the lower basin, take the weight when it was placed in the upper. The remainder will be the loss of weight by immersion. Divide the reserved product by the loss by immersion, and the quotient will be the specific gravity of the solid with regard to distilled water at the standard temperature and pressure."

To find the specific gravity of a fluid proceed thus: "To the weight of the gravimeter add the weight required in the upper basin to sink it in the unknown fluid. Again, to the weight of the gravimeter add the

weight required in the same manner to sink it in distilled water. Divide the first sum by the latter, and the quotient will be the specific gravity of the fluid in question." See SPECIFIC GRAVITY, HYDROSTATICS, and HYDROMETER.

GRAVING, in the sea language, is bringing a ship aground, and then burning off with furze, reed, or broom, all the filth and foulness that sticks to her bottom withoutboard, in order to pay her anew.

GRAVITATION. See ATTRACTION, and GRAVITY.

GRAVITATION, *laws of*, are as follows:

1. It is common to all bodies, and mutual between them. 2. It is proportional to the quantity of matter in bodies. 3. It is exerted every way from the centre of the attracting body in right-lined directions. 4. It decreases as the squares of the distances increase: thus, if a body at A on the earth's surface, distant one semidiameter from the centre C, weighs 36.00 pounds, it will, at the distance of 2, 3, 4, 5, 6, semidiameters, weigh 9.00, 4.00, 2.25, 1.45, 1.00 pounds, which numbers decrease as the squares of the distances increase. The truth of this proposition is not to be had from experiments; the utmost distance we convey bodies to, from the surface of the earth, bearing no proportion to their distance from its centre, but is sufficiently clear from the motions observed by the heavenly bodies. Hence we learn, that all bodies have gravity, or are heavy, and that there is no such thing as absolute levity in nature; and by the second law, the gravitation of all bodies is proportional to the quantity of matter they contain: and hence, since bodies of equal bulk are found to have unequal quantities of matter, it evidently follows, that a vacuum, or solid void of matter, must necessarily exist, and that an absolute plenum is a doctrine unphilosophical, and equally false and absurd.

Also from the third law it follows, that all bodies descending freely by their gravity, tend towards the earth in right lines perpendicular to its surface, and with equal velocities, abating for the resistance of the air; as is evident from the second law above.

Again, since the gravitation is always as the quantity of matter, and inversely as the square of the distance, it follows, that were the internal parts of the earth a perfect void, or hollow concavity, a body placed any where therein would be absolutely light, or void of gravity; but supposing the earth a solid body throughout, the gravitation from the surface to the centre will decrease with the distance, or it will be directly proportional to the distance from the centre.

Gravitation being found by many experiments and observations to affect all the matter of bodies equally, we have hence more reason, says Mr. Maclaurin, to conclude its universality, since it appears to be a power that acts not only at the surfaces of bodies, and on such bodies as are removed at a distance from them, but to penetrate into their substances, and into that of all other bodies, even to their centres, to affect their internal parts with the same force as the external, to be obstructed in its action by no intervening body or obstacle, and to admit of no kind of variation in the same matter, but from its different distances only from that to which it gravitates.

This action of gravity on bodies arises

from its action on their parts, and is the aggregate of these actions; so the gravitations of bodies must arise from the gravity of all their particles towards each other. The weight of a body towards the earth arises from the gravity of the parts of that body: the gravity of a mountain towards the earth arises from the gravitation of all the parts of the mountain towards it; the gravitation of the northern hemisphere towards the southern arises from the gravitation of all its parts towards it; and if we suppose the earth divided into two unequal segments, the gravitation of the greater towards the lesser arises from the gravitation of all the parts of the greater towards the lesser. In the same manner the gravity of the whole earth, one particle being excepted, toward that particle, must arise from the quantity of gravitation of all the other particles of the earth towards that particle; every particle, therefore, of the earth gravitates towards every other particle: and for the same reason every particle in the solar system gravitates towards every other particle in it.

GRAVITY, in physiology, the natural tendency of bodies towards a centre.

Gravity may be distinguished into particular and general.

Particular GRAVITY, is that which respects the earth, or by which bodies descend, or tend towards the centre of the earth; the phenomena or properties of which are as follow:

1. All circumterrestrial bodies tend towards a point, which is either accurately or very nearly the centre of magnitude of the terraqueous globe. Not that it is meant that there is really any virtue or charm in the point called the centre, by which it attracts bodies; but because this is the result of the gravitation of bodies towards all the parts of which the earth consists.

2. This point or centre is fixed within the earth, or at least has been so considered as far as any authentic history reaches. For a consequence of its shifting, though ever so little, would be the overflowing of the low lands on that side of the globe towards which it should approach. Dr. Hailey suggests, that it would well account for the universal deluge, to have the centre of gravitation removed for a time towards the middle of the then inhabited world; for the change of its place but the 2000th part of the radius of the earth, or about two miles, would be sufficient to lay the tops of the highest hills under water.

3. In all places equidistant from the centre of the earth, the force of gravity is nearly equal. Indeed all parts of the earth's surface are not at equal distances from the centre, because the equatorial parts are higher than the polar parts by about 17 miles; as has been proved by the necessity of making the pendulum shorter in those places, before it will swing seconds. In the New Petersburg Transactions, vol. 6 and 7, M. Kraft gives a formula for the proportion of gravity in different latitudes on the earth's surface, which is this:

$$y = (1 + 0.0052848 \sin^2 \lambda) g;$$

where g denotes the gravity at the equator, and y the gravity under any other latitude λ .

4. Gravity equally affects all bodies, without regard either to their bulk, figure, or matter: so that, abstracting from the resistance of the medium, the most compact and

loose, the greatest and smallest bodies, would all descend through an equal space in the same time; as appears from the quick descent of very light bodies in an exhausted receiver. The space which bodies do actually fall in vacuo, is $16\frac{1}{2}$ feet in the first second of time, in the latitude of London; and for other times, either greater or less than that, the spaces descended from rest are directly proportional to the squares of the times, while the falling body is not far from the earth's surface.

5. This power is the greatest at the earth's surface, whence it decreases both upwards and downwards, but not both ways in the same proportion; for upwards the force of gravity is, as we have seen, less, or decreases, as the square of the distance from the centre, above the surface, the force would be only one-fourth of what it is at the surface; but below the surface the power decreases in such a manner, that its intensity is in the direct ratio of the distance from the centre; so that at the distance of half a semidiameter from the centre, the force would be but half what it is at the surface; at one-third of a semidiameter the force would be one-third, and so on.

6. As all bodies gravitate towards the earth, so does the earth equally gravitate towards all bodies; as well as all bodies towards particular parts of the earth, as hills, &c. which has been proved by the attraction a hill has upon a plumb-line, insensibly drawing it aside. Hence the gravitating force of entire bodies consists of that of all their parts: for by adding or taking away any part of the matter of a body, its gravity is increased or decreased in the proportion of the quantity of such proportion to the whole mass. Hence also the gravitating powers of bodies, at the same distance from the centre, are proportional to the quantities of matter in the bodies.

General or universal GRAVITY, is that by which all the planets tend to one another, and indeed by which all the bodies and particles of matter in the universe tend towards one another.

The existence of the same principle of gravitation in the superior regions of the heavens, as on the earth, is one of the great discoveries of Newton, who made the proof of it as easy as that on the earth. At first it would seem that this was only conjecture with him: he observed that all bodies near the earth, and in its atmosphere, had the property of tending directly towards it; he soon conjectured that it probably extended much higher than any distance to which we could reach, or make experiments; and so on, from one distance to another, till he at length saw no reason why it might not extend as far as to the moon, by means of which she might be retained in her orbit as a stone in a sling is retained by the hand; and if so, he next inferred, why might not a similar principle exist in the other great bodies in the universe, the sun and all the other planets, both primary and secondary, which might all be retained in their orbits, and perform their revolutions, by means of the same universal principle of gravitation.

These conjectures he soon realized and verified by mathematical proofs. Kepler had found out, by contemplating the motions of the planets about the sun, that the area described by a line connecting the sun and planet, as this revolved in its orbit, was al-

ways proportional to the time of its description; or that it described equal areas in equal times, in whatever part of its orbit the planet might be, moving always so much the quicker as its distance from the sun was less. And it is also found that the satellites, or secondary planets, respect the same law in revolving about their primaries. But it was soon proved by Newton, that all bodies moving in any curve line described on a plane, and which, by radii drawn to any certain point, describe areas about the point proportional to the times, are impelled or acted on by some power tending towards that point. Consequently the power by which all these planets revolve, and are retained in their orbits, is directed to the centre about which they move, viz. the primary planets to the sun, and the satellites to their several primaries.

Again, Newton demonstrated, that if several bodies revolve with an equable motion in several circles about the same centre, and that if the squares of their periodical times are in the same proportion as the cubes of their distances from the common centre, then the centripetal forces of the revolving bodies, by which they tend to their central body, will be in the reciprocal or inverse ratio of the squares of the distances. Or if bodies revolve in orbits approaching to circles, and the apses of those orbits are at rest, then also the centripetal forces of the revolving bodies will be reciprocally proportional to the squares of the distances. But it had been agreed on by the astronomers, and particularly Kepler, that both these cases obtain in all the planets. And therefore he inferred, that the centripetal forces of all the planets are reciprocally proportional to the squares of the distances from the centres of their orbits.

Upon the whole it appears, that the planets are retained in their orbits by some power which is continually acting upon them: that this power is directed towards the centre of their orbits: that the intensity or efficacy of this power increases upon an approach towards the centre, and diminishes on receding from the same, and that in the reciprocal duplicate ratio of the distances: and that, by comparing this centripetal force of the planets with the force of gravity on the earth, they are found to be perfectly alike, as may easily be shewn in various instances. For example, in the case of the moon, the nearest of all the planets. The rectilinear spaces described in any given time by a falling body, urged by any powers, reckoning from the beginning of its descent, are proportional to those powers. Consequently the centripetal force of the moon revolving in her orbit, will be to the force of gravity on the surface of the earth, as the space which the moon would describe in falling during any small time, by her centripetal force towards the earth, if she had no circular motion at all, to the space of a body near the earth would describe in falling by its gravity towards the same.

Now by an easy calculation of those two spaces, it appears that the former force is to the latter, as the square of the semidiameter of the earth is to the square of that of the moon's orbit. The moon's centripetal force therefore is equal to the force of gravity; and consequently these forces are not different, but they are one and the same: for if they were different, bodies acted on by the

two powers conjointly would fall towards the earth with a velocity double to that arising from the sole power of gravity.

It is evident therefore that the moon's centripetal force, by which she is retained in her orbit, and prevented from running off in tangents, is the very power of gravity of the earth extended thither. See Newton's Princip. lib. 1, prop. 45, and lib. 3, prop. 3; where the numeral calculation may be seen at full length.

The moon therefore gravitates towards the earth, and reciprocally the earth towards the moon. And this is also farther confirmed by the phenomena of the tides.

The like reasoning may also be applied to the other planets. For as the revolutions of the primary planets round the sun, and those of the satellites of Jupiter and Saturn round their primaries, are phenomena of the same kind with the revolution of the moon about the earth; and as the centripetal powers of the primary are directed towards the centre of the sun, and those of the satellites towards the centres of their primaries; and, lastly, as all these powers are reciprocally as the squares of the distances from the centres, it may safely be concluded that the power and cause are the same in all.

As the moon, therefore, gravitates towards the earth, and the earth towards the moon; so do all the secondaries to their primaries, and these to their secondaries; and so also do the primaries to the sun, and the sun to the primaries. Newton's Princip. lib. 3, prop. 4, 5, 6; Greg. Astron. lib. 1, sect. 7, prop. 46 and 47.

The laws of universal gravity are the same as those of bodies gravitating towards the earth, before laid down.

Cause of gravity. Various theories have been advanced by the philosophers of different ages to account for this grand principle of gravitation. The ancients, who were only acquainted with particular gravity, or the tendency of sublunar bodies towards the earth, aimed no farther than to establish a system that might answer the more obvious phenomena of it. Some hints, however, are found concerning the gravitation of celestial bodies in the account given of the doctrine of Thales and his successors; and it would seem that Pythagoras was still better acquainted with it, and which it is supposed he had in view in what he taught concerning the harmony of the spheres.

Aristotle and the Peripatetics content themselves with referring gravity or weight to a native inclination in heavy bodies to be in their proper place or sphere, the centre of the earth. And Copernicus ascribes it to an innate principle in all parts of matter, by which, when separated from their wholes, they endeavour to return to them again the nearest way.

Kepler, in his preface to the Commentaries concerning the planet Mars, speaks of gravity as of a power that was mutual between bodies; and says that the earth and moon tend towards each other, and would meet in a point so many times nearer to the earth than to the moon, as the earth is greater than the moon, if the motions did not hinder it. He adds, that the tides arise from the gravity of the waters towards the moon. To him we also owe the important discovery of

the analogy between the distances of the several planets from the sun, and the periods in which they complete their revolutions, viz. that the squares of their periodical times are always in the same proportion as the cubes of their mean distances from the sun. However, Kepler, Gassendi, Gilbert, and others, ascribe gravity to a certain magnetic attraction of the earth; conceiving the earth to be one great magnet continually emitting effluvia, which take hold of all bodies, and draw them towards the earth. But this is inconsistent with the several phenomena.

Des Cartes and his followers, Rohault, &c. attribute gravity to an external impulse or trusion of some subtle matter. By the rotation of the earth, say they, all the parts and appendages of it necessarily endeavour to recede from the centre of rotation; but whence they cannot all actually recede, as there is no vacuum or space to receive them. But this hypothesis, founded on the supposition of a plenum, is overthrown by what has been since proved of the existence of a vacuum.

Dr. Halley, despairing of any satisfactory theory, chooses to have immediate recourse to the agency of the Deity. So Dr. Clarke, from a view of several properties of gravity, concludes that it is no adventitious effect of any motion, or subtle matter, but an original and general law impressed by God on all matter, and preserved in it by some efficient power penetrating the very solid and intimate substance of it; being found always proportional, not to the surfaces of bodies or corpuscles, but to their solid quantity and contents. It should therefore be no more enquired why bodies gravitate, than how they came to be first put in motion.

Gravesande, in his *Introduct. ad Philos. Newton.* contends, that the cause of gravity is utterly unknown; and that we are to consider it no otherwise than as a law of nature originally and immediately impressed by the Creator, without any dependance on any second law or cause at all. Of this he thinks the three following considerations sufficient proof. 1. That gravity requires the presence of the gravitating or attracting body: so that the satellites of Jupiter, for example gravitate towards Jupiter, wherever he may be. 2. That the distance being supposed the same, the velocity with which bodies are moved by the force of gravity, depends on the quantity of matter in the attracting body; and the velocity is not changed, whatever the mass of the gravitating body may be. 3. That if gravity depends on any known law of motion, it must be some impulse from an extraneous body; so that as gravity is continual, a continual stroke must also be required. Now if there is any such matter continually striking on bodies, it must be fluid and subtle enough to penetrate the substance of all bodies: but how shall a body subtle enough to penetrate the substance of the hardest bodies, and so rare as not sensibly to hinder the motion of bodies, be able to impel vast masses towards each other with such force? How does this force increase the ratio of the mass of the body, towards which the other body is moved? Whence is it that all bodies move with the same velocity, the distance and body gravitated to being the same? Can a fluid which only acts on the surface either of the bodies themselves, or their internal particles, communicate such a quantity of

motion to bodies, which in all bodies shall exactly follow the proportion of the quantity of matter in them?

Mr. Cotes goes yet farther. Giving a view of Newton's philosophy, he asserts that gravity is to be ranked among the primary qualities of all bodies; and deemed equally essential to matter as extension, mobility, or impenetrability. *Præfat. ad Newt. Princip.* But Newton himself disclaims this notion; and to shew that he does not take gravity to be essential to bodies, he declares his opinion of the cause; choosing to propose it by way of query, not being yet sufficiently satisfied about its experiments. Thus, after having shewn that there is a medium in nature vastly more subtle than air, by whose vibrations sound is propagated, by which light communicates heat to bodies, and by the different densities of which the refraction and reflection of light are performed; he proceeds to enquire: "Is not this medium much rarer within the dense bodies of the sun, stars, planets, and comets, than in the empty celestial spaces between them? And in passing from them to greater distances, doth it not grow denser and denser perpetually, and thereby cause the gravity of those great bodies towards one another, and of their parts towards the bodies; every body endeavouring to recede from the denser parts of the medium towards the rarer?"

"For if this medium be supposed rarer within the Sun's body than at its surface, and rarer there than at the hundredth part of an inch from his body, and rarer there than at the fiftieth part of an inch from his body, and rarer there than at the orb of Saturn; I see no reason why the increase of density should stop any where, and not rather be continued through all distances from the Sun to Saturn, and beyond.

"And though this increase of density may at great distances be exceeding slow; yet if the elastic force of this medium be exceeding great, it may suffice to impel bodies from the denser parts of the medium towards the rarer with all that power which we call gravity.

"And that the elastic force of this medium is exceeding great, may be gathered from the swiftness of its vibration. Sounds move about 1140 English feet in a second of time, and in seven or eight minutes of time they move about 100 English miles: light moves from the Sun to us in about seven or eight minutes of time; which distance is about 70,000,000 English miles, supposing the horizontal parallax of the Sun to be about twelve seconds; and the vibrations, or pulses of this medium, that they may cause the alternate fits of easy transmission, and easy reflection, must be swifter than light, and by consequence above 7000000 times swifter than sounds; and therefore the elastic force of this medium, in proportion to its density, must be above 7000000×7000000 (that is, above 490,000,000,000) times greater than the elastic force of the air is in proportion to its density: for the velocities of the pulses of elastic mediums are in a subduplicate ratio of the elasticities and the rarities of the mediums taken together.

"As magnetism is stronger in small loadstones than in great ones, in proportion to their bulk; and gravity is stronger on the

surface of small planets than those of great ones, in proportion to their bulk; and small bodies are agitated much more by electric attraction than great ones: so the smallness of the rays of light may contribute very much to the power of the agent by which they are refracted; and if any one should suppose that æther (like our air) may contain particles which endeavour to recede from one another (for I do not know what this æther is), and that its particles are exceedingly smaller than those of air, or even than those of light; the exceeding smallness of such particles may contribute to the greatness of the force by which they recede from one another, and thereby make that medium exceedingly more rare and elastic than air, and of consequence exceedingly less able to resist the motions of projectiles, and exceedingly more able to press upon gross bodies by endeavouring to expand itself." *Optics, p. 325, &c.*

GRAVITY, in mechanics, denotes the tendency of bodies towards the centre of the earth. That part of mechanics which considers the equilibrium, or motion of bodies arising from gravity or weight, is particularly called statics.

Gravity in this view is distinguished into absolute and relative.

Absolute GRAVITY is that with which a body descends freely and perpendicularly through an unresisting medium. See **MECHANICS**.

Relative GRAVITY is that with which a body descends on an inclined plane, or through a resisting medium, or as opposed by some other resistance. See **MECHANICS**.

GRAVITY, in hydrostatics. The laws of bodies gravitating in fluids make the business of hydrostatics.

Gravity is here divided into absolute and specific.

Absolute, or true GRAVITY, is the whole force with which the body tends downwards.

Specific GRAVITY, is the relative, comparative, or apparent gravity in any body, in respect of that of an equal bulk or magnitude of another body; denoting that gravity or weight which is peculiar to each species or kind of body, and by which it is distinguished from all other kinds.

In this sense a body is said to be specifically heavier than another, when under the same bulk it contains a greater weight than that other; and reciprocally the latter is said to be specifically lighter than the former. Thus, if there are two equal spheres, each one foot in diameter; the one of lead, and the other of wood: since the leaden one is found heavier than the wooden one, it is said to be specifically, or in specie, heavier; and the wooden one specifically lighter.

This kind of gravity is by some called relative; in opposition to absolute gravity, which increases in proportion to the quantity or mass of the body.

Laws of the specific gravity of bodies.

I. If two bodies are equal in bulk, their specific gravities are to each other as their weights, or as their densities.

II. If two bodies are of the same specific gravity or density, their absolute weights will be as their magnitudes or bulks.

III. In bodies of the same weight, the

specific gravities are reciprocally as their bulks.

IV. The specific gravities of all bodies are in a ratio compounded of the direct ratio of their weights and reciprocal ratio of their magnitudes. And hence again the specific gravities are as the densities.

V. The absolute gravities or weights of bodies are in the compound ratio of their specific gravities and magnitudes or bulks.

VI. The magnitudes of bodies are directly as their weights, and reciprocally as their specific gravities.

VII. A body specifically heavier than a fluid, loses as much of its weight when immersed in it, as is equal to the weight of a quantity of the fluid of the same bulk or magnitude.

Hence, since the specific gravities are as the absolute gravities under the same bulk; the specific gravity of the fluid, will be to that of the body immersed, as the part of the weight lost by the solid, is to the whole weight.

And hence the specific gravities of fluids are as the weights lost by the same solid immersed in them.

VIII. *To find the specific gravity of a fluid or of a solid.* On one arm of a balance suspend a globe of lead by a fine thread, and to the other fasten an equal weight, which may just balance it in the open air. Immerse the globe into the fluid, and observe what weight balances it then, and consequently what weight is lost, which is proportional to the specific gravity as above. And thus the proportion of the specific gravity of one fluid to another is determined by immersing the globe successively in all the fluids, and observing the weights lost in each, which will be the proportions of the specific gravities of the fluids sought.

This same operation determines also the specific gravity of the solid immersed, whether it is a globe, or of any other shape or bulk, supposing that of the fluid known. For the specific gravity of the fluid is to that of the solid, as the weight lost is to the whole weight.

Hence also may be found the specific gravity of a body that is lighter than the fluid, as follows:

IX. *To find the specific gravity of a solid that is lighter than the fluid, as water, in which it is put.* Annex to the lighter body another that is much heavier than the fluid, so that the compound mass may sink in the fluid. Weigh the heavier body and the compound mass separately, both in water and out of it; then find how much each loses in water, by subtracting its weight in water from its weight in air; and subtract the less of these remainders from the greater.

Then, As this last remainder,

Is to the weight of the light body in air,

So is the specific gravity of the fluid,

To the specific gravity of that body.

X. The specific gravities of bodies of equal weight, are reciprocally proportional to the quantities of weight lost in the same fluid. And hence is found the ratio of the specific gravities of solids, by weighing in the same fluids, masses of them that weigh equally in air, and noting the weights lost by each.

The specific gravities of many kinds of bodies, both solid and fluid, have been determined by various authors. It will be suffi-

cient here to give those of some of the most usual bodies that have been determined with the greater certainty. The numbers in this table express the number of avoirdupoise ounces in a cubic foot of each body, that of common water being just 1000 ounces, or 62½ lb.

A TABLE

OF THE SPECIFIC GRAVITIES OF DIFFERENT BODIES, ARRANGED ALPHABETICALLY.

Metals.

| | |
|--|-------|
| Antimony, crude | 4064 |
| — glass of | 4046 |
| — molten | 6702 |
| Arsenic, glass of, natural | 3594 |
| — molten | 5763 |
| — native orpiment | 5452 |
| Bismuth, molten | 9823 |
| — native | 9020 |
| — ore of, in plumes | 4371 |
| Brass, cast, not hammered | 8396 |
| — ditto, wiredrawn | 8544 |
| — cast, common | 7824 |
| Cobalt, molten | 7812 |
| — blue glass of | 2441 |
| Copper, not hammered | 7788 |
| — the same wiredrawn | 8878 |
| — ore of soft copper, or natural verdigr. | 3572 |
| Gold, pure, of 24 carats, melted, but not hammered | 19258 |
| — the same hammered | 19362 |
| — Parisian standard, 22 car. not hammered | 17486 |
| — the same hammered | 17589 |
| — guinea of Geo. II. | 17150 |
| — guinea of Geo. III. | 17629 |
| — Spanish gold coin | 17655 |
| — Holland ducats | 19352 |
| — trinket standard, 20 car. not hammered | 15709 |
| — the same hammered | 15775 |
| Iron, cast | 7207 |
| — bar, either hardened or not | 7788 |
| Steel, neithered tempered nor hardened | 7833 |
| — hardened, but not tempered | 7840 |
| — tempered and hardened | 7818 |
| — ditto not hardened | 7816 |
| Iron, ore prismatic | 7355 |
| — ditto specular | 5218 |
| — ditto lenticular | 5012 |
| Lead, molten | 11352 |
| — ore of, cubic | 7587 |
| — ditto horned | 6072 |
| — ore of black lead | 6745 |
| — ditto white lead | 4059 |
| — ditto ditto vitreous | 6558 |
| — ditto red lead | 6027 |
| — ditto saturnite | 5925 |
| Manganese, striated | 4756 |
| Molybdena | 4738 |
| Mercury, solid, or congealed | 15632 |
| — fluent | 13568 |
| — natural calx of | 9230 |
| — precipitate per se | 10871 |
| — precipitate, red | 8399 |
| — brown cinnabar | 10218 |
| — red cinnabar | 6902 |
| Nickel, molten | 7807 |
| — ore of, called kupfernickel of Saxe | 6648 |
| — kupfernickel of Bohemia | 6607 |
| Platina, crude, in grains | 15602 |
| — purified, not hammered | 19500 |

| | |
|--|-------|
| Platina, purified, hammered | 20337 |
| — ditto wiredrawn | 21042 |
| — ditto rolled | 22069 |
| Silver, virgin, 12 deniers, fine, not hammered | 10744 |
| — ditto hammered | 10511 |
| — Paris standard | 10175 |
| — shilling of Geo. II. | 10000 |
| — shilling of Geo. III. | 10534 |
| — French coin | 10408 |
| Tin, pure Cornish, melted, and not hardened | 7291 |
| — the same hardened | 7299 |
| — of Malacca, not hardened | 7296 |
| — the same hardened | 7307 |
| — ore of, red | 6935 |
| — ore of, black | 6901 |
| — ore of, white | 6008 |
| Tungsten | 6066 |
| Uranium | 6440 |
| Wolfram | 7119 |
| Zinc, molten | 7191 |

Precious stones.

| | |
|-----------------------------------|------|
| Beryl, or aqua-marine, oriental | 3549 |
| — ditto occidental | 2723 |
| Chrysolite, of the jewellers | 2782 |
| — of Brazil | 2692 |
| Chrystal, pure rock of Madagascar | 2653 |
| — of Brazil | 2653 |
| — European | 2655 |
| — rose-coloured | 2670 |
| — yellow | 2654 |
| — violet, or amethyst | 2654 |
| — white amethyst | 2651 |
| — Carthaginian | 2657 |
| — black | 2654 |
| Diamond, white oriental | 3521 |
| — rose-coloured oriental | 3531 |
| — orange ditto | 3550 |
| — green ditto | 3524 |
| — blue ditto | 3525 |
| — Brazilian | 3444 |

Weight and specific gravities of different gases.

| | Fahrenheit's therm. 55° | Barom. 30 inch. |
|-------------------|-------------------------|-----------------|
| | Spec. grav. | Wt. cub. foot. |
| Atmospheric air | 1.2 | 525.0 grs. |
| Hydrogenous gas | 0.1 | 43.75 |
| Oxygenous gas | 1.435 | 627.812 |
| Azotic gas | 1.182 | 517.125 |
| Nitrous gas | 1.4544 | 636.333 |
| Ammoniac. gas | .7311 | 319.832 |
| Sulphur. acid gas | 2.7611 | 1207.978 |

In this table the weights and specific gravities of the principal gases are given, as they correspond to a state of the barometer and thermometer which may be chosen for a medium. The specific gravity of any one gas to that of another will not conform to exactly the same ratio under different degrees of heat and other pressures of the atmosphere, because the various expansions by no means follow the same law.

These numbers being the weight of a cubic foot, or 1728 cubic inches, of each of the bodies, in avoirdupois ounces, by proportion the quantity in any other weight, or the weight of any other quantity, may be readily known.

For example. Required the content of an irregular block of millstone which weighs 1 cwt. or 112 lb. or 1792 ounces. Here, as $2500 : 1792 :: 1728 : 1228\frac{4}{5}$ cubic inches the content.

Ex. 2. To find the weight of a block of granite, whose length is 63 feet, and breadth and thickness each 12 feet; being the dimensions of one of the stones of granite in the walls of Balbec. Here $63 \times 12 \times 12 = 9072$ feet is the content of the stone; therefore as $1 : 9072 :: 3500 \text{ oz. } 31752000 \text{ oz. or } 885 \text{ tons } 18 \text{ cwt. } 3 \text{ qrs.}$ the weight of the stone.

XI. A body descends in a fluid specifically lighter, or ascends in a fluid specifically heavier, with a force equal to the difference between its weight and that of an equal bulk of the fluid.

XII. A body sinks in a fluid specifically heavier, so far as that the weight of the body is equal to the weight of a quantity of the fluid of the same bulk as the part immersed. Hence, as the specific gravity of the fluid, is to that of the body, so is the whole magnitude of the body, to the magnitude of the part immersed.

XIII. The specific gravities of equal solids are as their parts immersed in the same fluid.

The several theorems here delivered are both demonstrable from the principles of mechanics, and are also equally conformable to experiment, which answers exactly to the calculation. See HYDROSTATICS.

GRAVITY, in music. Gravity is that modification of any sound by which it becomes deep or low in respect of some other sound: the gravity of sounds depends on the thickness and distension of the chords, or the length and diameter of the pipes, and in general on the mass, extent, and tension, of the sonorous bodies. The larger and more lax are the bodies, the slower will be the vibrations, and the graver the sounds.

GRAUSTEIN, in mineralogy, is a rock composed of small grains of felspar and hornblende, which graduate into each other, and form a mass almost homogenous of an ash-grey colour. It contains olivine and augite.

GREAT-CIRCLE SAILING, the manner of conducting a ship in, or rather pretty near, the arch of a great circle, that passes through the zenith of the two places, viz. whence she came, and to which she is bound.

GREEN-CLOTH, a board, or court of justice, held in the compting-house of the king's household, composed of the lord-steward, and officers under him, who sit daily. To this court are committed the charge and oversight of the king's household in matters of justice and government, with a power to correct all offenders, and to maintain the peace of the verge, or jurisdiction of the court-royal; which is every way about two hundred yards from the last gate of the palace where his majesty resides. It takes its name from a green cloth spread over the board where they sit. Without a warrant first obtained from this court, none of the king's servants can be arrested for debt.

GREEN-FINCH, in ornithology. See FRINGILLA.

GREEN-HOUSE, or conservatory, a house in a garden contrived for sheltering and preserving the most tender and curious exotic plants, which, in our climate, will not bear to be exposed to the open air during the winter season. These are generally large and beautiful structures, equally ornamental and useful.

GREENLAND COMPANY. A joint stock of 40,000l. was by statute to be raised by subscribers, who were incorporated for 14 years from the 1st of October, 1693, and the company to use the trade of catching whales, &c. into and from Greenland and the Greenland seas. They make bye-laws for the government of the persons employed in their ships, &c. Stat. 4 and 5 W. III. cap. 17. This company was farther encouraged by parliament in 1696; but partly by unskilful management, and partly by real losses, it was under the necessity of entirely breaking up, before the expiration of the term assigned to it, ending in 1707. But any person who will adventure to Greenland for whale-fishing shall have all the privileges granted to the Greenland company by 1 Anne, cap. 16, and thus the trade was again laid open. Any subjects may import whale-fins, oil, &c. of fish caught in the Greenland seas, without paying any customs, &c. Stat. 10 Geo. I. cap. 16. And ships employed in the Greenland fishery are to be of a given burden, provided with boats, so many men, fishing-lines, harping-irons, &c. and be licensed to proceed; and on their return shall be paid 20s. per ton bounty for whale-fins, &c. imported. 6 Geo. II. cap. 33. The bounty was afterwards increased, but has been lately diminished; and since this diminution the trade has increased. See BALENA, and FISHERY.

GREGORIAN CALENDAR. See CALENDAR, and EPOCH.

GREGORIAN EPOCH, the epocha or time whence the Gregorian calendar or computation took place.

GREGORIAN YEAR, the Julian year corrected or modelled, in such a manner as that three secular years, which in the Julian account are bissextile, are here common years, and only every fourth secular year is made a bissextile year.

The Julian computation is more than the solar year by eleven minutes, which in 131 years amounts to a whole day. By this calculation the vernal equinox was anticipated 10 days from the time of the general council of Nice, held in the year 325 of the christian era, to the time of pope Gregory XIII. who therefore caused 10 days to be taken out of the month of October, in 1582, to make the equinox fall on the 21st of March, as it did at the time of that council; and to prevent the like variation for the future, he ordered that three days should be abated in every 400 years, by reducing the leap-year at the close of each century for three successive centuries to common years, and retaining the leap-year at the close of each fourth century only. This was at that time esteemed as exactly conformable to the true solar year, but it is found not to be strictly just, because that in 400 years it gets one hour and twenty minutes; and consequently in 7200 years, a whole day.

The greatest part of Europe have long

used the Gregorian style; but Great Britain retained the Julian till the year 1752, when by act of parliament this style was adjusted to the Gregorian; since which time Sweden, Denmark, and other European states, who computed time by the Julian account, have followed this example.

GREWIA, a genus of the polyandria order, in the gynandria class of plants, and in the natural method ranking under the 37th order, columnifera. The calyx is pentaphyllous; there are five petals, each with a nectariferous scale at the base; the berry is quadrilocular. The species are 13. The most remarkable are:

1. The *occidentalis*, with oval crenated leaves, has long been preserved in many curious gardens both in England and Holland. It is a native of the Cape of Good Hope, and grows to the height of 10 or 12 feet. The stem and branches greatly resemble those of the small-leaved elm, the bark being smooth, and of the same colour with that when young. The leaves are also very like those of the elm, and fall off in autumn. The flowers are produced singly along the young branches from the wings of the leaves, and are of a bright purple colour.

2. The *africana*, with oval spear-shaped serrated leaves, is a native of Senegal in Africa, whence its seeds were brought by Mr. Adanson. In this country it rises with a shrubby stalk five or six feet high, sending out many lateral branches, with a brown hairy bark, and garnished with spear-shaped serrated leaves; but the plants have not flowered in Britain.

The first sort, though a native of a warm climate, will bear the open air in this country; only requiring to be sheltered in a greenhouse during the winter time. It may be propagated by cuttings or layers planted in pots filled with soft loamy earth. The second sort is tender, and must be kept constantly in a warm bark-stove. In summer they require a large share of the free air to be admitted to them, and should have water three or four times a week in warm weather; but in the winter they must be sparingly watered. The negroes of Senegal consider a decoction of the bark of this last species as a never-failing remedy against venereal complaints.

GREWT, among miners, signifies earth of a different colour from the rest, found on the banks of rivers as they are searching for mines.

GREYHOUND. See **CANIS**.

GRIAS, a genus of the monogynia order, in the polyandria class of plants, and in the natural method ranking with those of which the order is doubtful. The corolla is tetrapetalous; the calyx quadrifid; the stigma sessile and cruciform: the fruit is a plum with an eight-furrowed kernel. There is but one species, the *cauliflora*, or anchovy pear, a native of Jamaica. The leaves are nearly oval, and about three feet long. It has a straight stem, upon the upper part of which come forth the flowers. The fruit is large, and contains a stone with eight furrows. These fruits are eaten by the inhabitants.

GRIELUM, a genus of the pentagynia order, in the decandria class of plants. The calyx is quinquefid, there are five petals; the filaments persisting; and there are five monospermous seed-cases. There is one species, a herb of the Cape.

GRIFFON, in heraldry, an imaginary animal, feigned by the antients to be half eagle and half lion; by this form they intended to give an idea of strength and swiftness joined together, with an extraordinary vigilance in guarding the things entrusted to its care.

GRINDING, *trituration*, the reducing hard substances to fine powders, either by the mortar, or by way of levigation, upon a marble. See **MILLWORK**.

GRIPLE, in the sea language, is a piece of timber stayed against the lower piece of the stern, from the foremast end of the keel, joining with the knee of the head: its use is to defend the lower part of the stern from any injury; but it is often made the larger, to make the ship keep a good wind.

GRISLEA, a genus of the monogynia order, in the octandria class of plants, and in the natural method ranking under the 17th order, calycanthemæ. The calyx is quadrifid; and there are four petals, one from each incisure of it. The filaments are very long, ascending or turning upwards; the capsule is globose, superior, unilocular, and polyspermous. There are two species; one a tree of S. America, the other a shrub of the East Indies.

GRIST, in country-affairs, denotes corn ground, or ready for grinding. See **FLOUR-MILL**.

GRIT, a genus of argillaceous earths. Its texture is more or less porous, equable, and rough to the touch. It does not give fire with steel, nor effervesce with acids. When fresh broken and breathed upon, it exhales an earthy smell. Mr. Kirwan mentions two kinds; one from Hollington, near Uttoxeter, of a yellowish or whitish grey, and about the specific gravity of 2288. Another, from Kneppersley in Staffordshire, is of the specific gravity of 2568, and so infusible as to be used for fire-stones. According to Fabroni the grit-stone is of greater or less hardness, mostly of a grey, and sometimes of a yellowish colour, composed of a siliceous and micaceous sand, but rarely of a sparry kind; with greater or smaller particles closely compacted by an argillaceous cement. It gives some sparks with steel, is indissoluble for the most part in acids, and vitrifiable in a strong fire. It is used for millstones and whetstones, and sometimes for filtering-stones and for building.

GROGRAM, a kind of stuff, made of silk and mohair.

GRONOVIA, a genus of the monogynia order, in the pentandria class of plants, and in the natural method ranking under the 34th order, cucurbitaceæ. There are five petals and stamina inserted into a campanulated calyx; the berry is dry, monospermous, and inferior. There is one species, an annual of La Vera Cruz.

GROOM, a name particularly applied to several superior officers belonging to the king's household, as groom of the chamber, groom of the stole.

GROOVE, among miners, is the shaft or pit sunk into the earth, sometimes in the vein, and sometimes not.

GROOVE, among joiners, the channel made by their plough in the edge of a moulding, style, or rail, to put their pannels in, in wainscoting.

GROSS, in law-books, signifies absolute or independent on another; thus, an advowson in gross, is one distinct and separate from the manor.

GROSS also denotes the quantity of twelve dozen, of things sold by tale.

GROSS-BEAK, in ornithology. See **LOXIA**.

GROSS-WEIGHT, the whole weight of merchandizes, with their dust and dross; as also the bag or chest wherein they are contained. An allowance is usually made out of the gross weight for tare and tret. See **TARE**.

GROTESQUE, in sculpture and painting, something whimsical, extravagant, and monstrous; consisting either of things that are merely imaginary, and have no existence in nature, or of things so distorted, as to raise surprize and ridicule. Grotesque work is the same with what is sometimes called antique. The name is said to have taken its rise from the figures of this kind much used in adorning the grottos which in antient times were the tombs of eminent persons or families; such as that of Ovid, whose grotto was discovered near Rome about 100 years ago.

GROTTO, or **GROTTA**, a large deep cavern or den in a mountain or rock. The word is Italian, grotta; formed, according to Menage, &c. from the Latin crypta. Du Cange observes, that grotta was used in the same sense in the corrupt Latin. The ancient anchorites retired into dens and grottes, to apply themselves the more attentively to meditation. Okey-hole, Elden-hound, Peake's-hole, and Pool's-hole, are famous among the natural caverns or grottos of our country. The entrance to Okey-hole, on the south side of Mendip-hills, is in the fall of those hills, which is beset all about with rocks, and has near it a precipitate descent of near twelve fathoms deep, at the bottom of which there continually issues from the rocks a considerable current of water. The naked rocks above the entrance show themselves about 30 fathoms high, and the whole ascent of the hill above is about a mile, and is very steep. As you pass into this vault, you go at first upon a level; but advancing farther, the way is found to be rocky and uneven, sometimes ascending, and sometimes descending. The roof of this cavern, in the highest part, is about eight fathoms from the ground, but in many particular places it is so low, that a man must stoop to get along. The breadth is not less various than the height, for in some places it is five or six fathoms wide, and in others not more than one or two. It extends itself in length about two hundred yards. People talk much of certain stones in it, resembling men and women, and other things; but there is little matter of curiosity in these, being only shapeless lumps of a common spar. At the farthest part of the cavern there is a good stream of water, large enough to drive a mill, which passes all along one side of the cavern, and at length slides down about six or eight fathoms among the rocks, and then passing through the clefts of them, discharges itself into the valley. The river within the cavern is well stored with eels, and has some trouts in it; and these cannot have come from without, there being so great a fall near the entrance. In dry summers, a great number of frogs are seen all along this cavern, even to the farthest part of it; and on the roof of it, at certain places, hang vast numbers of bats, as they do in almost all caverns, the entrance of which is either level, or but slightly ascending or descending; and even in the more perpendicular ones they are sometimes found, provided they are not too narrow, and are

sufficiently high. The cattle that feed in the pastures through which this river runs have been known to die suddenly sometimes after a flood; this is probably owing to the waters having been impregnated, either naturally or accidentally, with lead ore.

Elden-hole is a huge profound perpendicular chasm, three miles from Buxton, ranked among the natural wonders of the Peak. Its depth is unknown, and is pretended to be unfathomable. Cotton tells us he sounded 884 yards, yet the plummet still drew. But he might easily be deceived, unless his plummet was very heavy; the weight of a rope of that length might well make the landing of the plummet scarcely perceivable.

Peak's-hole, and Pool's-hole, are two remarkable horizontal cavities under mountains; the one near Castleton, the other just by Buxton. They seem to have owed their origin to the springs which have their current through them; when the water had forced its way through the horizontal fissures of the strata, and had carried the loose earth away with it, the loose stones must fall down of course: and where the strata had few or no fissures, they remained entire; and so formed these very irregular arches, which are now so much wondered at. The water which passes through Pool's-hole is impregnated with particles of limestone, and has incrustated the whole cavern in such a manner that it appears as one solid rock.

In grottos are frequently found crystals of the rock, stalactites, and other natural conglaciations, and those often of an amazing beauty. M. Homberg conjectures, from several circumstances, that the marble pillars in the grotto of Antiparos vegetate or grow. That author looks on this grotto as a garden, in which the pieces of marble are the plants; and endeavours to show, that they could only be produced by some vegetative principle.

At Foligno in Italy is another grotto, consisting of pillars and orders of architecture of marble, with their ornaments, &c. scarcely inferior to those of art; but they all grow downwards: so that if this too is a garden, the plants are turned upside down.

Grotto del Cani, is a little cavern near Pozzuoli, four leagues from Naples, the steams whereof are of a mephitical or noxious quality; whence also it is called bocca venenosa, the poisonous mouth. "Two miles from Naples (says Dr. Mead), just by the Lago de Agnano, is a celebrated moëta, commonly called la Grotta del Cani, and equally destructive to all within the reach of its vapours. It is a small grotto about eight feet high, twelve long, and six broad; from the ground arises a thin, subtle, warm fume, visible enough to a discerning eye, which does not spring up in little parcels here and there, but in one continued stream, covering the whole surface of the bottom of the cave; having this remarkable difference from common vapours, that it does not, like smoke, disperse itself into the air, but quickly after its rise falls back again, and returns to the earth; the colour of the sides of the grotto being the measure of its ascent: for so far it is of a darkish-green, but higher only common earth. And as I myself found no inconvenience by standing in it, so no animal, if its head is above this mark, is the least injured. But when, as the manner is, a dog, or any other creature, is forcibly

kept below it; or, by reason of its smallness, cannot hold its head above it, it presently loses all motion, falls down as dead, or in a swoon; the limbs convulsed and trembling, till at last no more signs of life appear than a very weak and almost insensible beating of the heart and arteries; which, if the animal is left a little longer, quickly ceases too, and then the case is irrevocable; but if it is snatched out and laid in the open air, it soon comes to life again, and sooner if thrown into the adjacent lake." The steam or moëfite of the grotto del cani is now well known to be carbonic acid gas. See CHEMISTRY.

Grotta del Serpi, is a subterraneous cavern near the village of Sassa, eight miles from the city of Braccano in Italy, described by Kircher thus: "The grotta del serpi is big enough to hold two persons. It is perforated with several fistular apertures, somewhat in the manner of a sieve; out of which, at the beginning of the spring season, issues a numerous brood of young snakes of divers colours, but all free from any particular poisonous quality. In this cave they expose their lepers, paralytics, arthritics, and elephantiac patients, quite naked; where, the warmth of the subterraneous steams resolving them into a sweat, and the serpents clinging variously all around, licking and sucking them, they become so thoroughly freed of all their vicious humours, that upon repeating the operation for some time, they become perfectly restored." This cave Kircher visited himself; and found it warm, and every way agreeable to the description given of it. He saw the holes, and heard a murmuring hissing noise in them. Though he missed seeing the serpents, it not being the season of their creeping out, yet he saw a great number of their exuviae or sloughs, and an elm growing hard by laden with them. The discovery of the virtues of this cave was by the cure of a leper going from Rome to some baths near this place. Losing his way, and being benighted, he happened upon this cave. Finding it very warm, he pulled off his clothes; and being weary and sleepy, had the good fortune not to feel the serpents about him till they had wrought his cure.

Grotto, *Milky*, *Crypta Lactea*, a mile distant from the antient village of Bethlehem, is said to have been thus denominated on occasion of the Blessed Virgin, who let fall some drops of milk in giving suck to Jesus in this grotto. And hence it has been commonly supposed, that the earth of this cavern has the virtue of restoring milk to women that are grown dry, and even of curing fevers. Accordingly, they are always digging in it, and the earth is sold at a good rate to such as have folly enough to give credit to the fable. An altar has been built on the place, and a church just by it.

Grotto is also used for a little artificial edifice made in a garden, in imitation of a natural grotto. The outsides of these grottos are usually adorned with rustic architecture, and their inside with shell-work, fossils, &c. finished likewise with jets-d'eau or fountains, &c. A cement for artificial grottos may be made thus: Take 2 parts of white rosin, melt it clear, and add to it 4 parts of bees'-wax; when melted together, add 2 or 3 parts of the powder of the stone you design to cement, or so much as will give the cement the colour of the stone. With this cement,

the stones, shells, &c. after being well dried before the fire, may be cemented. Artificial red coral branches, for the embellishment of grottos, may be made in the following manner: Take clear rosin, dissolve it in a brass-pan, to every ounce of which add two drams of the finest vermilion; when you have stirred them well together, and have chosen your twigs and branches, peeled and dried, take a pencil and paint the branches all over whilst the composition is warm; afterwards shape them in imitation of natural coral. This done, hold the branches over a gentle coal-fire, till all is smooth and even as if polished. In the same manner white coral may be prepared with white lead, and black coral with lamp-black. A grotto may be built with little expence, of glass, cinders, pebbles, pieces of large flint, shells, moss, stones, counterfeit coral, pieces of chalk, &c. all bound or cemented together with the above-described cement.

GROUND, in painting, the surface upon which the figures and other objects are represented. See PAINTING.

GROUND-TACKLE, a ship's anchors, cables, and in general whatever is found necessary to make her ride safe at anchor.

GROUND-IVY, in botany. See GLECHOMA.

GROUND-Pine. See TEUCRIUM.

GROUNDAGE, a custom or tribute paid for the ground on which a ship stands in port.

GROUNDSEL, in botany, &c. See SENECEO.

GROUP, in painting and sculpture, is an assemblage of two or more figures of men, beasts, fruits, &c. which have some apparent relation to each other. See PAINTING.

GROUSE, or GROWSE. See TETRAO.

GROWAN, among the miners of Cornwall, a coarse gritty stone, of a greyish colour, which they are often obliged to dig through before they can reach the ore.

GRUNSTEIN, primitive, is a mixture of hornblende and felspar; and is divided into different varieties, according as its texture is granular or compact. See ROCKS PRIMITIVE.

GRY, a measure containing one-tenth of a line. A line is one-tenth of a digit, and a digit one-tenth of a foot, and a philosophical foot one-third of a pendulum whose diadromes, or vibrations, in the latitude of 45 degrees, are each equal to one second of time, or one-sixteenth of a minute.

GRYGALLUS, in ornithology, a name given to the urogallus, or tetrao. See TETRAO.

GRYLLUS, the locust, grasshopper, and cricket, in entomology, a genus of insects belonging to the order hemiptera. The generic character is, head inflexed, armed with jaws, and furnished with feelers. Antennæ, in most species, either filiform or setaceous. Wings four, deflex, convoluted: lower wings pleated. Hind legs formed for leaping: claws double on all the feet. There are 61 species, of which the following are most worthy of notice:

1. Among the most numerous species is the gryllus migratorius of Linnæus, or common migratory locust, which of all the insects capable of injuring mankind seems to possess the most dreadful powers of destruction. Legions of these animals are from time to time observed in various parts of the

world, where the havoc they commit is almost incredible: whole provinces are in a manner desolated by them in the space of a few days, and the air is darkened by their numbers: nay even when dead they are still terrible; since the putrefaction arising from their inconceivable number is such that it has been regarded as one of the probable causes of pestilence in the Eastern regions. This formidable locust is generally of a brownish colour, varied with pale red, or flesh-colour, and the legs are frequently blueish. In the year 1748, it appeared in irregular flights in several parts of Europe, as in Germany, France, and England; and in the capital itself and its neighbourhood great numbers were seen: they perished, however, in a short time, and were happily not productive of any material mischief, having been probably driven by some irregular wind out of their intended course, and weakened by the coolness of our climate.

From a paper published in the 18th volume of the Philosophical Transactions we find, that in the year 1693, swarms of this species of locust settled in some parts of Wales. Two vast flights were observed in the air not far from the town of Dolgalken, in Merionethshire: the others fell in Pembrokeshire. From a letter published in the 38th volume of the same work, it appears, that some parts of Germany, particularly in the march of Brandenburg, &c. suffered considerable injury from the depredations of these animals. They made their appearance in the spring of the year 1732, from flights which had deposited their eggs in the ground the preceding year. They attacked and devoured the young spike of the wheat, &c. and this chiefly by night, and thus laid waste many acres at a time beyond all hope of recovery. In the 46th volume of the same Transactions we find a description of the ravages of these animals in Wallachia, Moldavia, Transylvania, Hungary, and Poland, in the years 1747 and 1748.

"The first swarms entered into Transylvania in August 1747: these were succeeded by others, which were so surprizingly numerous, that when they reached the Red Tower, they were full four hours in their passage over that place; and they flew so close that they made a sort of noise in the air by the beating of their wings against one another. The width of the swarm was some hundreds of fathoms, and its height or density may be easily imagined to be more considerable, inasmuch as they hid the sun and darkened the sky, even to that degree, when they flew low, that people could not know one another at the distance of twenty paces; but as they were to fly over a river that runs in the valleys of the Red Tower, and could find neither resting-place nor food; being at length tired of their flight, one part of them lighted on the unripe corn on this side of the Red Tower, such as millet, Turkish wheat, &c.; another pitched on a low wood, where, having miserably wasted the produce of the land, they continued their journey, as if a signal had actually been given for a march. The guards of the Red Tower attempted to stop their irruption into Transylvania by firing at them; and indeed, where the balls and shot swept through the swarm, they gave way and di-

vided; but having filled up their ranks in a moment, they proceeded on their journey. In the month of September, some troops of them were thrown to the ground by great rains and other inclemency of the weather, and thoroughly soaked with wet: they crept along in quest of holes in the earth, dung, and straw; where being sheltered from the rains, they laid a vast number of eggs, which stuck together by a viscid juice, and were longer and smaller than what is commonly called an ant's egg (the chrysalis of the formica) very like grains of oats. In the spring of 1748, certain little blackish worms were seen lying in the fields and among the bushes, sticking together, and collecting in clusters, not unlike the hillocks of moles or ants. As nobody knew what they were, so there was little or no notice taken of them, and in May they were covered by the shooting of the corn sown in winter; but the subsequent June discovered what those worms were; for then, as the corn sown in spring was pretty high, these creatures began to spread over the fields, and become destructive to the vegetables by their numbers. At that time they differed little or nothing from our common grasshoppers; having their head, sides, and back, of a dark colour, with a yellow belly, and the rest of a reddish hue. About the middle of June, according as they were hatched sooner or later, they were generally a finger's length, or somewhat longer, but their shape and colour still continued. Towards the end of June they cast off their outward covering, and then it plainly appeared that they had wings; and as soon as any of them found themselves able to use their wings, they soared up, and by flying round the others, enticed them to join them. Wherever those troops happened to pitch, they spared no sort of vegetable: they ate up the young corn, and the very grass; but nothing was more dismal than to behold the lands in which they were hatched; for they so greedily devoured every thing green, before they could fly, that they left the ground quite bare.

"There is nothing to be feared in those places to which this plague did not reach before the autumn; for the locusts have not strength to fly to any considerable distance but in the months of July, August, and the beginning of September; and even then, in changing their places of residence, they seem to tend to warmer climates.

"Different methods are to be employed, according to the age and state of these insects; for some will be effectual as soon as they are hatched, others when they begin to crawl, and others when they begin to fly. It would be of great service to seek out the places where the females lodged; for nothing was more easy than carefully to visit those places in March and April, and to destroy their eggs or little worms with sticks or briars; but in the summer, when they have marched out of their spring-quarters, and have invaded the corn-fields, &c. it is almost impossible to extirpate them without thoroughly thrashing the whole piece of land that harbours them with sticks or flails, and thus crushing the locust with the produce of the land. Finally, when the corn is ripe or nearly so, there is no other method of getting rid of them, or even of diminishing their numbers, than to surround the ground with

a multitude of people, who might fright them away with bells, brass vessels, and all other sorts of noise. But even this method will not succeed till the sun is pretty high.

"It will likewise be of use, where a large troop of them has pitched, to dig a long trench, of an ell width and depth, and place several persons along its edges, provided with brooms, while another numerous set of people form a semicircle that takes in both ends of the trench, and encompasses the locusts; and by making the noise above-mentioned, drive them into the trench, out of which if they attempt to escape, those on the edges are to sweep them back, and then crush them with their brooms and stakes, and bury them by throwing in the earth again. But when they have begun to fly, there should be horsemen upon the watch in the fields, who, upon any appearance of the swarm taking wing, should immediately alarm the neighbourhood by a certain signal, that they might come and fright them from their lands by all sorts of noise; and if, tired with flying, they happen to pitch on a waste piece of land, it will be very easy to kill them with sticks and brooms in the evening or early in the morning, while they are wet with the dew; or any time of the day in rainy weather, for then they are not able to fly."

We have before observed, that the locusts which fell in several parts of England, and in particular in the neighbourhood of the metropolis, in the year 1748, were evidently some straggling detachments from the vast flights which in that year visited many of the inland parts of the European continent.

The ravages of locusts in various parts of the world, at different periods, are recorded by numerous authors. In the year 593 of the Christian era, after a great drought, these animals appeared in such vast legions as to cause a famine in many countries. In 677 Syria and Mesopotamia were overrun by them. In 852, immense swarms took their flight from the Eastern regions into the West, flying with such a sound that they might have been mistaken for birds: they destroyed all vegetables, not sparing even the bark of trees and the thatch of houses; and devoured the corn so rapidly, as to destroy, on computation, a hundred and forty acres in a day: their daily marches or distances of flight were computed at twenty miles; and these were regulated by leaders or kings, who flew first, and settled on the spot which was to be visited at the same hour the next day by the whole legion: these marches were always undertaken at sunrise. These locusts were at length driven by the force of winds into the Belgic ocean, and being thrown back by the tide and left on the shores, caused a dreadful pestilence by their smell. In 1271, all the corn-fields of Milan were destroyed; and in the year 1339 all those of Lombardy. In 1541, incredible hosts afflicted Poland, Wallachia, and all the adjoining territories, darkening the sun with their numbers, and ravaging all the fruits of the earth.

2. One of the largest species of locust yet known is the *gryllus cristatus* of Linnaeus, which is five or six times the size of the *gryllus migratorius*, and, together with some others of the larger kind, is made use of in some parts of the world as an article of food:

they are eaten both fresh and salted, in which last state they are publicly sold in the markets of some parts of the Levant. The quantity of edible substance which they afford is but small, especially in the male insects; but the females, on account of the ovaries, afford a more nutritious sustenance.

The *gryllus cristatus* is a highly beautiful animal; being of a bright red, with the body annulated with black; and the legs varied with yellow: the upper wings tessellated with alternate variegations of dark and pale green; the lower with transverse undulated streaks: the length of the animal from head to tail is about four inches, and the expanse of wings from tip to tip, when fully extended, hardly less than seven inches and a half.

3. Greatly allied to the preceding is the *gryllus dux*; it is of the same size and general appearance, but has the body green; the upper wings brown, with the front edge green; and the lower wings red, with numerous black spots disposed in such a manner as to form transverse streaks. It is a native of South America and the West Indian islands.

4. The *gryllus viridissimus* of Linnæus is one of the largest European species, and is often seen during the decline of summer in our own country. It is wholly of a pale grass-green, with a slight blueish cast on the head and under part of the thorax, which is marked above by a longitudinal reddish-brown line: the length of the insect, from the mouth to the tips of the wings, is about two inches and a half: the female is distinguished by a long sword-shaped process at the end of the body, being the instrument with which she pierces the ground in order to deposit her eggs: it consists of a pair of valves, through the whole length of which the eggs are protruded: they are of an oblong form, and of a pale brown colour.

5. The *gryllus verrucivorus* is also found in some parts of England, and is of an equal size with the *viridissimus*, but of a reddish-brown colour, with darker variegations; this animal, according to Linnæus, is frequently applied by the people of Sweden to warts on the hands, which it is suffered to bite off, and is said thus to prevent their return.

6. But of all the British insects of this genus the *gryllus gryllotalpa* or mole-cricket is by far the most curious; and in its colour and manners differs greatly from the rest. It is of an uncouth, and even formidable aspect, measuring more than two inches in length; and is of a broad and slightly flattened shape, of a dusky brown colour, with a ferruginous cast on the under parts, and is readily distinguished by the extraordinary structure of its fore-legs, which are excessively strong, and furnished with very broad feet, divided into several sharp, claw-shaped, segments, with which it is enabled to burrow under ground in the manner of a mole: the lower wings, which when expanded are very large, are, in their usual state, so complicated under the very short and small upper wings or sheaths, that their ends alone appear, reaching, in a sharpened form, along the middle of the back; the abdomen is terminated by a pair of sharp-pointed, lengthened, hairy processes, nearly equalling the length of the antennæ in front, and contributing to give this animal an appearance in some degree similar to that of a *blatta*.

The mole-cricket emerges from its subterraneous retreats only by night, when it creeps about the surface, and occasionally employs its wings in flight. It prepares for its eggs an oval nest, measuring about two inches in its longest diameter: this nest is situated a hand's breadth below the surface of the ground: it is accurately smoothed within, and is furnished with an obliquely curved passage leading to the surface. The eggs are about two hundred and fifty or three hundred in number, nearly round, of a deep brownish yellow colour, and of the size of common shot: on the approach of winter, or any great change of weather, these insects are said to remove the nest, by sinking it deeper, so as to secure it from the power of frost; and when the spring commences, again raising it in proportion to the warmth of the season, till at length it is brought so near the surface as to receive the full influence of the air and sunshine; but should unfavourable weather again take place, they again sink the precious deposit, and thus preserve it from danger. The eggs are usually deposited in the months of June or July, and the young are hatched in August. At their first exclusion they are about the size of ants, for which, on a cursory view, they might be mistaken; but on a close inspection are easily known by their broad feet, &c. In about the space of a month they are grown to the length of more than a quarter of an inch: in two months upwards of three quarters; and in three months to the length of more than an inch. Of this length they are usually seen during the close of autumn, after which they retire deep beneath the surface; not appearing again till the ensuing spring. During their growth they cast their skin three or four times.

The mole-cricket lives entirely on vegetables, devouring the young roots of grasses, corn, and various esculent plants, and commits great devastation in gardens. It is found in most parts of Europe, and in the northern parts of Asia and America.

7. The *tettigonia* or grasshopper, well known in our meadows, belongs to this genus.

8. The *acheta* or cricket, of which there are two varieties, the hearth and the field cricket.

9. The *griseus* is found in Italy. (See Plate Nat. Hist. fig. 215.)

10. The *stridulus* inhabits most parts of Europe. (See Plate Nat. Hist. fig. 216.)

GRYPHITES, in natural history, in English crow's-stone, an oblong fossil shell, very narrow at the head, and becoming gradually wider to the extremity, where it ends in a circular limb; the head or beak of this is very hooked or bent inward. They are frequently found in our gravel or clay-pits, in many counties. There are three or four distinct species of them; some are extremely rounded and convex on the back, others less so; and the plates of which they are composed, are in some smaller and thinner, in others thicker and larger, in specimens of the same bigness.

GUAIAECUM, *lignum vitæ*, or *pockwood*; a genus of the monogynia order, in the decandria class of plants, and in the natural method ranking under the 14th order, grui-

nales. The calyx is quinquefid and unequal; the petals five, and inserted into the calyx; the capsule is angulated, and trilocular or quinquelocular. The species are 4: 1. The officinale, or common *lignum vitæ* used in medicine, is a native of the West India islands and the warmer parts of America. (See Plate Nat. Hist. fig. 217.) There it becomes a large tree, having a hard, brittle, brownish bark, not very thick. The wood is firm, solid, ponderous, very resinous, of a blackish yellow colour in the middle, and of a hot aromatic taste. The smaller branches have an ash-coloured bark, and leaves divided by pairs of a bright green colour. The flowers are produced in clusters at the end of the branches, and are composed of oval concave petals of a fine blue colour. 2. The *sanctum*, with many pairs of obtuse lobes, and many small lobes placed along the mid-rib by pairs of a darker green colour than those of the foregoing sort. The flowers are produced in loose bunches towards the end of the branches, and are of a fine blue colour, with petals fringed on the edges. This species is also a native of the West India islands, where it is called *bastard lignum vitæ*. 3. The *afrum*, with many blunt-pointed leaves, is a native of the Cape of Good Hope. The plants retain their leaves all the year, but have never yet flowered in this country. 4. The *dubium*, a native of the South Seas.

The first species can only be propagated by seeds, which must be procured from the countries where it naturally grows. They must be sown fresh in pots, and plunged into a good hotbed, where they will come up in six or eight weeks. While young, they may be kept in a hotbed of tan-bark under a frame during the summer; but in autumn they must be removed into the bark stove, where they should constantly remain. The second sort may be propagated the same way; but the third is to be propagated by layers, and will live all the winter in a good greenhouse.

The wood of the first species is of very considerable use both in medicine and in the mechanical arts. It is so compact and heavy as to sink in water. The outer part is often of a pale-yellowish colour; but the heart is blacker, or rather of a deep brown. Sometimes it is marbled with different colours. It is so hard as to break the tools which are employed in felling it, and is therefore seldom used as fire-wood, but is of great use to the sugar-planters for making wheels and cogs to sugar-mills. It is also frequently wrought into bowls, mortars, and other utensils. It is brought over hither in large pieces of four or five hundredweight each; and from its hardness and beauty is in great demand for various articles of turnery ware.

The wood, gum, bark, fruit, and even the flowers of this tree, have been found to possess medicinal virtues; but it is only the 3 first, and more particularly the wood and resin, which are now in general use in Europe. The wood has little or no smell, except when heated, or while rasping, and then a slight aromatic one is perceived. When chewed, it impresses a mild acrimony, biting the palate and fauces. Its pungency resides in its resinous matter, which it gives out in some degree to water by boiling, but spirit extracts it wholly.

The resin is obtained by wounding the bark in different parts of the body of the tree, or by what has been called jagging. It exudes copiously from these wounds, though gradually; and when a quantity is found accumulated upon the several wounded trees, hardened by exposure to the sun, it is gathered and packed in small kegs for exportation. This resin is of a friable texture, of a deep greenish colour, and sometimes of a reddish hue; it has a pungent acrid taste, but little or no smell unless heated. The tree also yields a spontaneous exudation from the bark, which is called the native gum, and is brought to us in small irregular pieces, of a bright semipellucid appearance, and differs from the former in being much purer.

Guaiacum was first introduced into Europe as a remedy for the venereal disease, and appears to have been used in Spain so early as 1508. The great success attending its administration before the proper use of mercury was known, brought it into such repute, that it is said to have been sold for seven old crowns a pound. It did not, however, continue to maintain its reputation; but was found generally to fail where the disease was inveterate, and was at length superseded by mercury, to which it now only serves occasionally as an adjuvant. The general virtues of guaiacum, are those of a warm stimulating medicine, strengthening the stomach and other viscera, and remarkably promoting the urinary and cuticular discharges: hence in cutaneous eruptions, it is deemed eminently useful; as well as in the rheumatism when given in a sufficient dose. The resin is the most active, and the efficacy of the wood, &c. depends upon the quantity of this contained in them. The resin is given from a few grains to a scruple or half a dram, which last dose proves for the most part considerably purgative. Dissolved in spirit of wine, and afterwards combined with water, by means of mucilage or the yolk of egg, or in form of the simple or volatile tincture, it is much employed in gout and chronic rheumatism. These last have been given to the extent of half an ounce twice a day, and are sometimes usefully combined with tincture of opium. See RESINS.

GUARDIAN, one appointed by the wisdom and policy of the law, to take care of a person and his affairs, who by reason of his imbecility and want of understanding is incapable of acting for his own interest; and it seems by our law, that his office originally was to instruct the ward in the arts of war, as well as those of husbandry and tillage, that when he came of age he might be the better able to perform those services to his lord, whereby he held his own land. 2 Bac. Abr. 672.

There are several kinds of guardians, as, guardian by nature, guardian by the common law, guardian by statute, guardian by custom, guardian in chivalry, guardian in soccage, and guardian by appointment of the lord chancellor.

Guardian by nature, is the father or mother; and here it should be observed, that by the common law every father has a right of guardianship of the body of his son and heir, until he attains the age of twenty-one years. Co. Lit. 84.

This guardianship extends no further than the custody of the infant's person. 1 Inst. 84.

It yields as to the custody of the person, to guardianship in soccage, where the title to both guardianships concur in the same individuals. 1 Inst. 88 b.

But guardianship in soccage ending at 14, it seems that after that age, the father or other ancestor, having a like title to both guardianships, becomes guardians by nature till the infant's age of 21. Carth. 384.

Lastly, the father may disappoint the mother, and other ancestors, of the guardianship by nature, by appointing a testamentary guardian under the statutes 4 and 5 P. et M. and 12 Car. II.

Guardian by nature, has only the care of the person and education of the infant, and has nothing to do with his lands merely in virtue of his office; for such guardian may be though the infant have no lands at all, which a guardian in soccage cannot. Co. Lit. 88.

Guardian by the common law. If a tenant in soccage dies, his heir being under 14, whether he is his issue or cousin, male or female, the next of blood to the heir, to whom the inheritance cannot descend, shall be guardian of his body and land till his age of fourteen; and although the nature of soccage tenure is in some measure changed from what it originally was, yet it is still called soccage tenure, and the guardian in soccage is still only where lands of that kind, as most of the lands in England now are, descend to the heir within age; and though the heir after 14 may choose his own guardian, who shall continue till he is 21, yet as well the guardian before 14, as he whom the infant shall think fit to choose after 14, are both of the same nature, and have the same office and employment assigned to them by the law, without any intervention or direction of the infant himself: for they were therefore appointed, because the infant in regard of his minority, was supposed incapable of managing himself and his estate, and consequently derive their authority not from the infant, but from the law: and that is the reason they transact all affairs in their own name, and not in the name of the infant, as they would be obliged to do if their authority was derived from him. Co. Lit. 87.

Hence the law has invested them, not with a bare authority only, but also with an interest till the guardianship ceases; and to prevent their abuse of this authority and interest, the law has made them accountable to the infant, either when he comes to the age of 14 years, or at any time after, as he thinks fit; and therefore are not to have any thing to their own use, as the guardian in chivalry had. Co. Lit. 90. a.

Guardian by statute. By the common law, no person could appoint a guardian, because the law had appointed one, whether the father was tenant by knight service, or in soccage. 3 Co. 37.

The first statute that gave the father a power of appointing, was the 4 and 5 P. and M. c. 8. which provides under severe penalties, such as fine and imprisonment for years, that no one shall take away any maid or woman child unmarried, being within the age of sixteen years, out of or from the posses-

sion, custody, or governance, and against the will, of the father of such maid or woman child, or of such person or persons to whom the father of such maid or woman child, by his last will and testament, or by any other act in his life-time, has or shall appoint, assign, bequeath, give, or grant the order, keeping, education and government, of such maid or woman child. 1 Sid. 362.

In the construction of this statute, the following opinion has been holden. That a testamentary guardian, or one formed according to this statute, comes in loco parentis, and is the same in office and interest with a guardian in soccage, and differs only as to the *modus habendi*, or in a few particular circumstances; as first that it may be held for a longer time, viz. till the heir attains the age of 21, whereas before it was but 14; secondly, it may be by other persons held, for before it was the next of kindred not inheritable could have it; and now who the father names shall have it. Vaugh. 178.

Guardian by custom. By the custom of the city of London, the custody and guardianship of orphans under age, unmarried, belongs to the city. 2 Bac. Abr. 675.

By the custom of Kent, where any tenant died, his heir being within age, the lord of the manor might and did commit the guardianship to the next relation within the court of justice in whose jurisdiction the land was; but the lord was bound on all occasions to call him to account, and if he did not see that the accounts were fair, the lord himself was bound to answer it. This province the lord chancellor has taken from inferior courts, only in Kent, where these customs are continued.

Guardian in chivalry. By the common law, if tenant by knight-service had died, his heir male being under the age of twenty-one years, the lord shall have the land holden of him, till such heir had arrived at that age, because till then he was not intended to be able to do such service; and such lord had likewise the custody of the body of the infant, to bring him up, and inure him to martial discipline, and was therefore called guardian in chivalry. Co. Lit. 74. This privilege of wardship is now abolished.

Guardian in soccage. Guardians in soccage are also called guardians by the common law. Wardship is incident to tenure in soccage, but of a nature very different from that which was formerly incident to knight-service; for if the inheritance descends to an infant under 14, the wardship of him does not, nor ever did, belong to the lord of the fee; because in this tenure, no military or other personal service being required, there was no occasion for the lord to take the profits in order to provide a proper substitute for his infant tenant. Co. Lit. 84.

Guardian by appointment of the lord chancellor. It is not easy to state how this jurisdiction was acquired; it is certainly of no very ancient date, though now indisputable: for it is clearly agreed, that the king, as *pater patriæ*, is universal guardian of all infants, idiots, and lunatics, who cannot take care of themselves; and as this care cannot be exercised otherwise than by appointing them proper curators or committees, it seems also agreed, that the king may, as he has done, delegate the authority to his chancellor; and that therefore at this day, the court of

chancery is the only proper court, that has jurisdiction in appointing and removing guardians, and in preventing them and others from abusing their persons or estates. 2 Inst. 14. And as the court of chancery is now vested with this authority, hence in every day's practice, we find that court determining, as to the right of guardianship, who is the next of kin, and who the most proper guardian; as also orders are made by that court on petition or motion, for the provision of infants during any dispute therein; as likewise guardians removed or compelled to give security; they and others punished for abuses committed on infants, &c.

GUARDIAN of the spiritualities, the person to whom the spiritual jurisdiction of any diocese is committed, during the time the see is vacant. A guardian of the spiritualities may likewise be either such in law, as the archbishop is of any diocese within his province; or by delegation, as he whom the archbishop or vicar-general for the time appoints. Any such guardian has power to hold courts, grant licences, dispensations, probates of wills, &c.

GUAPERVA. See **CHETODON**.

GUAREA, a genus of the class and order octandria monogynia. The cal. is four-cleft; pet. four; nect. cylindric, bearing the anthers at its mouth; caps. four-valved, four-celled; seeds solitary. There is one species, a tree of the West Indies.

GUDGEON, in ichthyology. See **CYPRINUS**.

GUDGEONS, in a ship, are the eyes drove into the stern-post, into which the pintles of the rudder go, to hang it.

In vol. XI. of the Transactions of the Society for the Encouragement of Arts, &c. we have the following account of a gudgeon on an improved construction for the upright shafts of mills. "This gudgeon is formed of hard steel, and works on a hard steel bed; is circular, three inches in diameter, and three-fourths of an inch thick: from its upper side a rib projects, which being fixed in the bottom of an upright shaft, the gudgeon works horizontally on a square bed: and that now in the possession of the society has worked in a mill whose wheel and shaft weighed nearly six tons; and though it had continued to work seven years, had lost very little of its surface. It ran in a square box of cast iron, having oil therein: and a notch along the whole of the face of the gudgeon admits the oil to insinuate itself between the gudgeon and the bed."

GUETTARDA, a genus of the heptandria order, in the monœcia class of plants, and in the natural method ranking under the 38th order, tricocœ. The male calyx is cylindrical; the corolla cleft into seven parts, and funnel-shaped. The female calyx cylindrical; the corolla cleft into seven parts; one pistil, and the fruit a dry plum. There are four species, trees of the East and West Indies.

GUILANDINA, the nickar tree; a genus of the monogynia order, in the decandria class of plants, and in the natural method ranking under the 33d order, lomentacœ. The calyx is monophyllous and salver-shaped; the petals inserted into the neck of the calyx, nearly equal. The seed-vessel a legumen. The species are six: the most

remarkable are, 1. The bonduc, or yellow nickar. 2. The bonducella, or grey nickar. These are climbing plants, natives of the West Indies, where they rise to the height of 12 or 14 feet: the flowers come out at the wings of the stalks, and are composed of five concave yellow petals. They are succeeded by pods about three inches long and two broad, closely armed with slender spines, opening with two valves, each inclosing two hard seeds about the size of children's marbles, of a yellowish colour. 3. The morninga, or morunga nickar, is a native of the island of Ceylon, and some places on the Malabar coast. It rises to the height of 25 or 30 feet, having flowers produced in loose bunches from the sides of the branches, and composed of an unequal number of petals.

These plants, being natives of warm climates, require to be kept through the winter in a stove in this country. They are propagated by seeds; but those of the first sort are so hard, that unless they are soaked two or three days in water before they are put into the ground, or placed under the pots in the tan-bed to soften their covers, they will remain for years without vegetating. The roots of the third sort are scraped when young, and used by the inhabitants of Ceylon and Malabar as those of horse-radish are in Europe. The wood dyes a beautiful blue colour. It is the lignum nephriticum of the dispensatories, and is brought over in large, compact, ponderous pieces, without knots, of a whitish or pale-yellow colour on the outside, and dark-coloured or reddish within: the bark is usually rejected. This wood imparts to water or rectified spirit a deep tincture; appearing, when placed between the eye and the light, of a golden colour; in other situations blue: pieces of another wood are sometimes mixed with it, which give only a yellow colour to water. The nephritic wood has scarcely any smell, and very little taste. It stands recommended in difficulty of urine, and all nephritic complaints, and is said to have this peculiar advantage; that it does not, like the warmer diuretics, heat or irritate the urinary passages. Practitioners, however, have not found these praises warranted by experience.

GUILD (from the Saxon guildan "to pay"), signifies a fraternity or company, because every one was gildare, that is, to pay something towards the charge and support of the company. As to the original of these guilds or companies, it was a law among the Saxons, that every freeman of fourteen years of age should find sureties to keep the peace, or be committed: upon which certain neighbours, consisting of ten families, entered into an association, and became bound for each other, either to produce him who committed an offence, or to make satisfaction to the injured party: that they might the better do this, they raised a sum of money among themselves, which they put into a common stock; and when one of their pledges had committed an offence, and was fled, then the other nine made satisfaction out of this stock, by payment of money according to the offence. Because this association consisted of ten families, it was called a decennary: and hence proceeded later kinds of fraternities. But as to the precise time when these guilds had their origin in England, there is nothing of certainty to be found: since they were in

use long before any formal licence was granted to them for such meetings. It seems to have been about the close of the eleventh century, says Anderson in his History of Commerce, vol. i. p. 70, that merchant-guilds, or fraternities, which were afterwards styled corporations, came first into general use in many parts of Europe. Mr. Madox, in his Firma Burgi, chap. i. § 9. thinks they were hardly known to our Saxon progenitors, and that they might be probably brought into England by the Normans, although they do not seem to have been very numerous in those days. The French and Normans might probably borrow them from the free cities of Italy, where trade and manufactures were much earlier propagated, and where possibly such communities were first in use. These guilds are now companies joined together, with laws and orders made by themselves, by the licence of the prince.

GUILD, in the royal boroughs of Scotland, is still used for a company of merchants, who are freemen of the borough. (See **BOROUGH**.) Every royal borough has a dean of guild, who is the next magistrate below the bailiff. He judges of controversies among men concerning trade; disputes between inhabitants touching buildings, lights, water-courses, and other nuisances; calls courts, at which his brethren of the guild are bound to attend; manages the common stock of the guild; and amerces and collects fines.

GUINEA-FIG. See **CAVIA**.

GUINEA-WORM. See **DRACUNCULUS**.

GUITAR, or **GUITARRA**, a musical instrument of the string-kind, with five double rows of strings, of which those that are bass, are in the middle, unless it be for the burden, an octave lower than the fourth.

GULA, or **GOLA**. See **ARCHITECTURE**.

GULES, in heraldry, signifies the colour red, which is expressed in engraving by perpendicular lines falling from the top of the escutcheon to the bottom.

GUM. A thick, transparent, tasteless fluid, which sometimes exudes from certain species of trees. It is very adhesive, and gradually hardens without losing its transparency; but easily softens again when moistened with water. The gum most commonly used is that which exudes from different species of the mimosa, particularly the nilotica. It is known by the name of gum arabic. Gum likewise exudes abundantly from the prunus avium, or common wild cherry-tree of this country.

Gum is usually obtained in small pieces like tears, moderately hard, and somewhat brittle while cold, so that it can be reduced by pounding to a fine powder. When pure it is colourless, but it has usually a yellowish tinge, and it is not destitute of lustre. It has no smell. Its taste is insipid. Its specific gravity varies from 1.31 to 1.48.

1. Gum undergoes no change from being exposed to the atmosphere; but the light of the sun makes it assume a white colour. Water dissolves it in large quantities. The solution which is known by the name of mucilage, is thick and adhesive: it is often used as a paste, and to give stiffness and lustre to linen. When spread out thin it soon dries, and has the appearance of a varnish; but it readily attracts moisture, and becomes glutinous. Water washes it away

entirely. When mucilage is evaporated the gum is obtained unaltered. This mucilaginous solution may be kept for years without undergoing putrefaction. Scarcely any vegetable substance is less liable to decomposition. At last, however, the odour of acetic acid becomes perceptible in it.

When gum is exposed to heat it softens and swells, but does not melt; it emits air-bubbles, blackens, and at last, when nearly reduced to charcoal, emits a low blue flame. This flame appears sooner if a flaming substance is held just above the gum. After the gum is consumed, there remains a small quantity of white ashes, composed chiefly of the carbonates of lime and potass.

2. It does not appear that gum is acted upon by oxygen gas. A solution of gum and water, when exposed to the air, soon becomes mouldy on the surface, but undergoes no farther change for a long time. The action of the simple combustibles on gum has scarcely been examined. Azotic gas seems to have no action on it whatever.

Gum does not act upon metals; but it has the property of combining with several of the metallic oxides, and forming compounds: at least, some of the salts occasion precipitates when dropt into solutions of gum. The most curious effect is that produced by the oxymuriatic acid of iron. When this salt, concentrated, is dropt into a very strong mucilage, the whole becomes a brown semitransparent jelly, which is not readily dissolved by water. When dried, the jelly becomes lighter-coloured, and assumes nearly the appearance of gum. Its taste is that of gum mixed with iron.

Liquid potass first converts gum into a substance not unlike curd, and then dissolves it. The solution is of a light amber-colour, and transparent. When long kept, the gum again falls into the state of curd. Alcohol throws down the gum in white flakes, still soluble in water; but it retains the potass obstinately, and is much more friable than before. Lime-water and ammonia likewise dissolve gum, and it may be afterwards separated little altered.

Charcoal powder, when mixed with a solution of gum in water, gives it a black colour, which cannot be removed by filtration, unless a very great proportion of the powder is added. In that case the water passes clear; but the whole of the gum is retained by the charcoal. Mr. Lowitz found that not less than 30 lbs. of charcoal powder must be mixed with water containing an ounce of gum dissolved in it, before the water is entirely deprived of the gum.

The vegetable acids dissolve gum without alteration; the strong acids decompose it. Sulphuric acid converts it into water, acetic acid, and charcoal. The same effect is said by Fourcroy to be produced by muriatic acid. But this is not accurate unless some heat is applied. When gum is dissolved in strong muriatic acid, a brown solution is obtained, which becomes perfectly transparent when diluted with water, while at the same time some charry matter falls. If the solution is now saturated with ammonia, evaporated to dryness, and the residue digested in alcohol, the alcohol assumes a deep-brown colour, and dissolves the whole except a very little sal ammoniac. The gum now bears some resemblance to sugar in its properties;

at least when heated it melts, and gives out a very strong smell of caramel.

Oxymuriatic acid converts gum into citric acid, according to the experiments of Vauquelin. He passed a current of oxymuriatic acid gas through a diluted solution of gum in water. In a few days almost the whole of the gum was acidified; and he detected citric acid by the formation of citrat of lime, soluble in water, and decomposable by oxalic acid. If nitric acid is slightly heated upon gum till it has dissolved it, and till a little nitrous gas is exhaled, the solution on cooling deposits saccharic acid. Malic acid is formed at the same time; and if the heat is continued, the gum is at last changed into oxalic acid. Thus no less than three acids are developed by the action of nitric acid on gum. We are indebted to Mr. Cruikshank for the most precise experiments on the quantity of oxalic acid obtainable from gum by nitric acid. By digesting 480 grains of it with six ounces of nitric acid, he obtained 210 grains of oxalic acid, and six grains of oxalat of lime.

Gum is insoluble in alcohol. When alcohol is poured into mucilage, the gum immediately precipitates; because the affinity between water and alcohol is greater than that between water and gum. The gum in this case is in the state of soft opaque white flakes. Neither is gum soluble in ether. It is not soluble in oils; but when triturated with a little oil it renders the oil miscible with water.

The action of the hydrosulphurets, sulphurets, phosphurets, and of most of the salts on gum, has not been examined with any attention.

Gum and sugar readily unite together by dissolving both in water. By gentle evaporation a perfectly transparent solid substance is obtained, which does not crystallize. When treated with alcohol it becomes white, opaque, and soft. The greater part of the sugar is dissolved, and the gum remains united to a small portion. It has a sweetish taste, and very much resembles in appearance the substance of which the nests of wasps are formed.

3. When gum is distilled in a retort, the products are water impregnated with a considerable quantity of pyromucous acid, or acetic acid combined with oil, a little empyreumatic oil, carbonic acid gas, and carburated hydrogen gas. When the pyromucous acid obtained by this process is saturated with lime, a quantity of ammonia is disengaged with which that acid had been combined. The charcoal which remained in the retort leaves behind it, after incineration, a little lime and phosphat of lime. Mr. Cruikshank, to whom we are indebted for these facts, gradually heated 480 grains of gum arabic to redness in a coated glass retort. The products were,

| | |
|---|---------|
| Pyromucous acid mixed with some oil | 210 gr. |
| Charcoal | 96 |
| Lime and a little phosphat of lime | 10 |
| Carburated hydrogen and carbonic acid gas | 164 |
| Total | 480. |

The pyromucous acid liquid contained less acid than what was obtained from an equal weight of sugar, in the proportion of 118 to 150. The gases consisted of 93 ounce measures of carbonic acid, and 180 of carbu-

rated hydrogen, composed of 5 parts charcoal to 1 of hydrogen. When the pyromucous acid was saturated with lime, ammonia was disengaged.

From these experiments it follows, that gum contains oxygen, hydrogen, carbon, azote, and lime. The lime may be detected by dropping nitric acid into a solution of gum; needleform crystals of sulphat of lime are slowly deposited. If we compare the products obtained by the distillation of sugar with those obtained from gum, we can scarcely doubt that the latter contains the greater proportion of carbon. As it yields less pyromucous acid, it is not improbable that it also contains less oxygen. Sugar is a triple compound; but gum contains five constituents.

4. The species of gum at present known amount to four; though it is likely that a more rigid examination of the vegetable kingdom will discover a greater number. These are gum arabic, gum tragacanth, cherry-tree gum, and the mucilage which is contained in the roots and leaves of many plants.

Gum arabic exudes from the mimosa nilotica, and other species of mimosa. It is the species described in the preceding part of this article.

5. Gum tragacanth is the produce of the astragalus tragacantha, a thorny shrub which grows in Candia and other islands of the Levant. The gum is said to exude about the end of June from the stem and larger branches, and soon dries in the sun. It is in the state of whitish vermiform pieces, not nearly so transparent as gum arabic. It is much stronger than gum arabic, not so easily dissolved in water, and is said to go farther. When Mr. Cruikshank distilled 480 grains of it in a glass retort, he obtained the following products:

| | |
|---|---------|
| Pyromucous acid | 245 gr. |
| Charcoal | 93 |
| Lime with some phosphat | 12 |
| Carbonic acid gas and carburated hydrogen gas | 130 |
| Total | 480 |

When the pyromucous acid was saturated with lime, a considerably greater proportion of ammonia was disengaged than from the pyromucous acid of gum arabic. The gases were 78 ounce-measures of carbonic acid, and 91 of carburated hydrogen. Hence we see that gum tragacanth contains more azote and lime, and perhaps more oxygen and less carbon, than gum arabic.

6. The prunus avium, the common cherry and plum trees, and the almond and apricot, likewise yield a gum which exudes in great abundance from natural or artificial openings in the stem. It is of a reddish-brown colour, in large masses, and much softer and more easily melted than gum arabic. But no precise set of experiments has been made to ascertain how far its properties coincide with those of the last two species.

7. Mucilage is contained in the roots and leaves of a vast number of plants. Almost all the bulbous roots and fleshy leaves yield it. For example, the roots of the hyacinthus nondescriptus, and the althea officinalis; the leaves of the althæa, of the malva sylvestris of many of the fuci, and of the greater num-

ber of the lichens; the seeds of flax, quinces, fenugrec, &c.

The bulbs of the hyacinth contain so much mucilage, that when dried they may be employed as a substitute for gum arabic. This was first made known to the public by Mr. Willis. A mucilage may be extracted from most of the stringy lichens by water, which likewise answers all the purposes of a solution of gum. This was first discovered by Lord Dundonald. The mucilaginous quality of most of the fuci is apparently much greater, though the mucilage obtained from them does not answer so well.

How far the mucilage extracted by water from these plants agrees with gum in its properties, has not been examined with much precision, if we except the mucilage of the hyacinth. From the experiments of Leroux, it appears that the mucilage of that plant is in every respect the same with gum. The bulbs are to be pounded, mixed with five times their weight of water, and subjected to the press. The residue is to be diluted afresh, and again pressed. The liquid thus obtained is to be allowed to repose for some days till it clarifies somewhat, and then evaporated to dryness. The gum remains.

8. It has been remarked by Mr. Barrow, and probably also by others, that all the plants which yield gum have an astringent bark. This rule, however, does not hold with respect to mucilage. Almost all the trees known to yield gum have been enumerated in the preceding part of this article. To attempt a list of all the plants containing mucilage, would, in the present state of our knowledge, be superfluous, even if it was possible. It exists most abundantly in young plants, and gradually disappears as they arrive at perfection. It forms a great proportion of the leaves and roots of many eatable plants.

9. Gum is a very nutritive food, though seldom employed for that purpose, except when in the state of mucilage. It is used frequently as a paste, and to give stiffness or lustre to linen. The calico-printers use it in great quantities to give their colours such a degree of consistency as prevents them from running upon the cloth. It forms an ingredient in ink for a similar reason. In medicine it forms the base of many mixtures.

GUM-RESINS. This class of vegetable substances has been long distinguished by physicians and apothecaries. It contains many active substances much employed in medicine; and they certainly possess a sufficient number of peculiar properties to entitle them to be ranked apart. Unfortunately these substances have not yet attracted much of the attention of chemists. Their properties and constituents of course are but imperfectly ascertained. They may, however, be distinguished by the following characters.

They are usually opaque, or at least their transparency is inferior to that of the resins. They are always solid, and most commonly very brittle, and have sometimes a fatty appearance.

When heated they do not melt as the resins do, neither are they so combustible. Heat, however, commonly softens them, and causes them to swell. They burn with a flame. They have almost always a strong

smell, which in several instances is alliaceous. Their taste also is often acrid, and always much stronger than that of the resins. They are partially soluble in water; but the solution is always opaque, and usually milky.

Alcohol dissolves only a portion of them. The solution is transparent; but when diluted with water it becomes milky; yet no precipitate falls, nor is any thing obtained by filtering the solution. Vinegar and wine likewise dissolve them partially; and the solution, like the aqueous, is opaque or milky.

The action of alkalies on them has been examined only by Mr. Hatchett. All of them tried by that celebrated chemist dissolved readily in alkaline solutions when assisted by heat. We may therefore consider them as soluble in alkalies like resins. Mr. Hatchett also found them acted on by nitric acid, and dissolved by it just as the resinous bodies.

Their specific gravity is usually greater than that of the resins. Their other properties still continue unknown. They all either exude spontaneously from plants, or are obtained by incisions. At first they seem to be in a liquid state; but they gradually harden when exposed to the air and weather.

They have been usually considered by chemists as composed of gum and resin; but their properties are not consistent with that supposition. They all contain a volatile oil, or a substance intermediate between an oil and resin. To this substance we are to ascribe the milky solution which they form with water. The other constituent, in most cases, bears a much closer resemblance to extractive than to gum; perhaps, then, we shall not err very far, if we consider the gum-resins as composed of a gum or an extractive substance, and a body intermediate between oil and resin; to which last they owe their most peculiar properties.

The gum-resins which have been hitherto applied to any useful purpose are chiefly the following:

1. *Galbanum*. It is obtained from the bubon galbanum, a perennial plant, and a native of Africa. When this plant is cut across a little above the root, a milky juice flows out, which soon hardens and constitutes galbanum. It comes to this country from the Levant in small pieces composed of tears, agglutinated together of a yellowish or white colour. Its taste is acrid and bitter, and its smell peculiar. Water, vinegar, and wine, dissolve most of it, but the solution is milky. Alcohol acts but feebly; when distilled it yields volatile oil in considerable quantity. Its specific gravity is 1.2.

2. *Ammoniac*. This substance is brought from the East Indies. Nothing certain is known concerning the plant which yields it; though from analogy it has been suspected to be a species of *ferula*. It is in small pieces, and has a yellowish-white colour. Its smell is somewhat like that of galbanum, but more pleasant; its taste is a nauseous sweet mixed with bitter. It does not melt. Water dissolves a portion of it; the solution is milky, but gradually lets fall a resinous portion. One-half is soluble in alcohol. It seems then to contain resin completely formed: specific gravity is 1.2. Mr. Hatchett found it soluble in alkalies.

3. *Olibanum*, is obtained from the juniperus lycia, and is chiefly collected in Arabia.

It is the frankincense of the ancients; it is in transparent brittle masses about the size of a chesnut. Its colour is yellow. It has little taste; and when burnt diffuses an agreeable odour. Alcohol dissolves it; and with water it forms a milky liquid. When distilled it yields a little volatile oil. Its specific gravity is 1.173.

4. *Sagapanum*. The plant which yields this gum-resin is not well known; but it is suspected to be the *ferula persica*. The substance itself is brought to Europe from Alexandria. It is commonly in tears agglutinated together: colour yellow; taste hot and bitter; smell alliaceous; softens between the fingers, but does not melt when heated: sparingly soluble in water, but almost completely soluble in alcohol. When distilled it yields a volatile oil.

5. *Asafetida*. This substance is obtained from the *ferula asafetida*, a perennial plant which is a native of Persia. When the plant is about four years old, its roots are dug up and cleaned. Their extremity being then cut off, a milky juice exudes, which is collected. Then another portion is cut off, and more juice exudes. This is continued till the roots are exhausted. The juice thus collected soon hardens, and constitutes asafetida. It comes to Europe in small grains of different colours, whitish, reddish, violet, brown: pretty hard, but brittle: its taste is acrid and bitter; its smell strongly alliaceous and fetid. It is imperfectly soluble both in alcohol and water; but, like the other gum-resins, has been but carelessly analysed. Its specific gravity is 1.327.

6. *Scammony*. This substance is obtained from the *convolvulus scammonia*, a climbing plant which grows in Persia. The roots when cut yield a milky juice; this when collected and allowed to harden constitutes scammony. Colour, dark grey; smell, peculiar and nauseous; taste, bitter and acrid; with water it forms a greenish-coloured opaque liquid. Alcohol dissolves the greatest part of it; it is usually mixed with the expressed juice of the root, and frequently also with other impurities, which alter its appearance. In medicine it operates as a strong cathartic. Its specific gravity is 1.235.

7. *Opoponax*. This substance is obtained from the *pastinaca opoponax*, a plant which is a native of the countries round the Levant. The gum resin, like most others, is obtained by wounding the roots of the plant. The milky juice when dried in the sun constitutes the opoponax. It is in lumps of a reddish yellow colour, and white within; smell peculiar; taste bitter and acrid; with water it forms a milky solution. Its specific gravity is 1.622.

8. *Gamboge*, or *gumgutt*. This substance is obtained from the *stalagmitis cambogioides*, a tree which grows wild in the East Indies. In Siam it is obtained in drops by wounding the shoots; in Ceylon it exudes from wounds of the bark. It is brought to Europe in large cakes. Its colour is yellow; it is opaque, brittle, and breaks vitreous; it has no smell, and very little taste; with water it forms a yellow turbid liquid. Alcohol dissolves it almost completely: and when mixed with water it becomes turbid, unless the solution contains ammonia; in that case acids throw down an insoluble yellow precipitate. It operates,

when taken internally, as a most violent cathartic; its specific gravity is 1.221. It appears that it was brought to Europe by the Dutch about the middle of the 17th century.

9. *Myrrh*. The plant from which this substance is obtained is unknown; if we believe Bruce, it belongs to the genus of *mimosa*. It grows in Abyssinia and Arabia: it is in the form of tears; colour reddish-yellow; when pure somewhat transparent, but it is often opaque: odour peculiar: taste bitter and aromatic: does not melt when heated, and burns with difficulty. With water it forms a yellow opaque solution: the solution in alcohol becomes opaque when mixed with water, but no precipitate appears: by distillation it yields oil: its specific gravity is 1.360; it is employed in medicine: Mr. Hatchett found it soluble in alkalies.

10. *Euphorbium*. This substance is obtained from the *euphorbia officinalis*. The milky juice which exudes from that plant, when dried in the sun, constitutes *euphorbium*: it is brought from Africa in small yellow tears; it has no smell, and is mostly soluble in alcohol: its specific gravity is 1.124. It is considered as poisonous.

11. Little is known concerning the substances called bdellium and caranna, reckoned among the gum-resins. The specific gravity of the first is 1.371, of the second 1.124. Bdellium was celebrated by the ancient physicians: it comes from Arabia. The substance extracted from ivy, and known by the name of *gummi hederæ*, is considered as a gum-resin. Its specific gravity is 1.294.

12. From the experiments made upon *ipecacuanha*, the root of the *cephelis ipecacuanana*, especially by Dr. Irvine, we learn that it also contains a gum-resin. The same remark applies to several other vegetable substances employed in medicine.

It deserves attention, that the gum-resins, when subjected to destructive distillation, yield all of them a portion of ammonia; a proof that they all contain azote. In this respect they agree with gum and extractives.

GUINEA, a gold coin struck in England. The value or rate of the guinea has varied. It was at first equal to 20 shillings; but by the scarcity of gold it was afterwards advanced to 21s. 6d.; though it is now sunk to 21s. The pound weight troy of gold is cut into 44 parts and a half, and each part makes a guinea, which is therefore equal to $\frac{2}{3}$ lb. or $\frac{2}{3}$ oz. or 5 dwts. $9\frac{1}{2}$ gr. This coin took its name, guinea, from the circumstance of the gold of which it was at first struck being brought from that part of Africa called Guinea, for which reason also it bore the impression of an elephant.

GUN, a fire-arm, or weapon of offence, which forcibly discharges a ball or other matter through a cylindrical tube, by means of inflamed gunpowder.

The word gun now includes most of the species of fire-arms; mortars and pistols being almost the only kind excepted from this denomination. They are divided into great and small guns; the former including all that are usually called cannon, ordnance, or artillery; and the latter including muskets, firelocks, carabines, musketoons, blunderbusses, fowling-pieces, &c.

The first hint of the invention of guns is in the works of Roger Bacon, who flourished in the 13th century. In a treatise written by him about the year 1280, he proposes to

apply the violent explosive force of gunpowder for the destruction of armies. And though it is certainly known that the composition of gunpowder is described by Bacon in the same work, yet the invention has usually, though improperly, been ascribed to Bartholdus Schwartz, a German monk, who it is said discovered it only in the year 1320; and the invention is related in the following manner: Schwartz having, for some purpose, pounded nitre, sulphur, and charcoal together, in a mortar, which he afterwards covered imperfectly with a stone, a spark of fire accidentally fell into the mortar, which setting the mixture on fire, the explosion blew the stone to a considerable distance. Hence it is probable that Schwartz might be taught the simplest method of applying it in war; for it rather seems that Bacon conceived the manner of using it to be by the violent effort of the flame unconfined, and which is indeed capable of producing astonishing effects. And the figure and name of mortars given to a species of old artillery, and their employment, in throwing large stone bullets at an elevation, very much favour this conjecture.

When, or by whom, guns were first made, is uncertain. It is known, however, that the Venetians used cannon at the siege of Claudia Jessa, now called Chioggia, in 1366, which were brought thither by two Germans, with some powder and leaden balls; as likewise in their wars with the Genoese in 1379. But before that, king Edward the Third made use of cannon at the battle of Cressy, in 1346, and at the siege of Calais, in 1347. Cannon were employed by the Turks at the siege of Constantinople, then in possession of the Christians, in 1394, and in that of 1452, which threw a weight of 100lb.; but they commonly burst at the first, second, or third firing. Louis the XIIth had one cast at Tours, of the same size, which threw a ball from the Bastille to Charenton: one of these extraordinary cannon was taken at the siege of Dieu, in 1546, by don John de Castro, and is now in the castle of St. Julian de Borra, 10 miles from Lisbon; the length of it is 20 feet 7 inches, its diameter at the middle 6 feet 3 inches, and it threw a ball of 100lb. weight. It has neither dolphins, rings, nor button; is of an unusual kind of metal; and it has a large Indostan inscription upon it, which says it was cast in 1400.

Cannon take their names from the weight of the proper ball. Thus, a piece that discharges a cast-iron ball of 24 pounds, is called a 24-pounder; one that carries a ball of 12 pounds, is called a 12-pounder; and so of the rest, divided into the following sorts, viz.

Ship-guns, consisting of 42, 36, 32, 24, 18, 12, 9, 6, and 3 pounders.

Garrison-guns, of 42, 32, 24, 18, 12, 9, and 6 pounders.

Battering-guns, of 24, 18, and 12 pounders.

Field-pieces, of 12, 9, 6, 3, 2, $1\frac{1}{2}$, 1, and $\frac{1}{2}$ pounders.

Mortars, it is thought, have been at least as ancient as cannon. They were employed in the wars of Italy, to throw balls of red-hot iron, stones, &c. long before the invention of shells.

Mr. Malter, an English engineer, first taught the French the art of throwing shells, which they practised at the siege of Motte in 1634. The method of throwing red-hot

balls out of mortars was first certainly put in practice at the siege of Stralsund in 1675 by the elector of Brandenburg; though some say in 1653, at the siege of Bremen.

Another species of ordnance has been long in use, by the name of howitzer, which is a kind of medium as to its length, between the cannon and the mortar, and is a very useful piece, for discharging either shells or large balls, which is done either at point-blank, or at a small elevation.

A new species of ordnance has lately been introduced by the Carron company, and thence called a carronade, which is only a very short howitzer, and which possesses the advantage of being very light and easy to work.

The species of guns before-mentioned, are now made chiefly of cast-iron; except the howitzer, which is of brass, as well as some cannon and mortars.

Muskets were first used at the siege of Rhege, in the year 1521. The Spaniards were the first who armed part of their foot with these weapons. At first they were very heavy, and could not be used without a rest. They had matchlocks, and did execution at a great distance. On their march the soldiers carried only the rests and ammunition, having boys to bear their muskets after them. They were very slow in loading, not only from the unwieldiness of their pieces, and because they carried the ball and powder separate, but from the time it took to prepare and adjust the match; so that their fire was not near so brisk as ours is now. Afterwards a lighter matchlock musket came in use; and they carried their ammunition in bandeliers, to which were hung several little cases of wood covered with leather, each containing a charge of powder. The muskets with rests were used as late as the beginning of the civil wars in the time of Charles the First. The lighter kind succeeded them, and continued till the beginning of the present century, when they also were disused, and the troops throughout Europe armed with firelocks. These are usually made of hammered iron.

GUNDELIA, a genus of the class and order syngenesia polygamia segregata. There is scarcely any calyx; what there is, is 5-flowered; cor. tubular, male and hermaphrodite; recept. chaffy; down none. There is one species, a herb of the Levant, having the habit of a thistle.

GUNNERA, a genus of the class and order gynandria diandria. The character is, ament. with 1-flowered scales; calyx and corolla none; germen, 2-toothed; styles 2; seed one. There is one species, a herb of the Cape.

GUNNERY, the art of charging, directing, and exploding fire-arms, as cannon, mortars, muskets, &c. to the best advantage.

Gunnery is sometimes considered as a part of the military art, and sometimes as a part of pyrotechny. To the art of gunnery too belongs the knowledge of the force and effect of gunpowder, the dimensions of the pieces, and the proportions of the powder and ball they carry, with the methods of maanging, charging, pointing, spunging, &c.

The first application of gunpowder to military affairs, it seems, was made soon after the year 1300, for which the proposal of friar Bacon, about the year 1280, for applying its enormous explosion to the destruction of

armies, might give the first hint; and Schwartz, to whom the invention of gunpowder has been erroneously ascribed, on account of the accident above-mentioned under the article GUN, might have been the first who actually applied it in this way.

The first species of artillery, however, which were charged with gunpowder and stone bullets of a prodigious size, were of very clumsy and inconvenient structure and weight. Thus, when Mahomet the 2d besieged Constantinople, in 1453, he battered the walls with stones of this kind, and with pieces of the calibre of 1200 pounds; which could not be fired more than four times a day.

For the last 200 years, the formation of cannon has been very little improved: the battering cannon now approved, are those that were formerly called demi-cannon, carrying a ball of 24 pounds weight; this weight having been found fully sufficient. The method also of making a breach, by first cutting off the whole wall as low as possible before its upper part is attempted to be beaten down, seems to be a considerable modern improvement in the practical part of gunnery; but the most considerable improvement in the practice, is the method of firing with small quantities of powder, and elevating the piece but a little, so that the bullet may just go clear of the parapet of the enemy, and drop into their works, called ricochet firing: for by this means the ball, coming to the ground at a small angle, and with a small velocity, does not bury itself, but bounds or rolls along a great way, destroying all before it.

The Italians were the first people that made any attempts to ascertain the theory of projectiles, which they did about the beginning of the 16th century. It was then determined, that the greatest range of a shot was when discharged at an elevation of 45 degrees; and that no part of the path described by a ball is a right line. See PROJECTILES.

Mr. Robins informs us, in the preface to his *New Principles of Gunnery*, that he had met with no more than four authors who had treated experimentally on this subject. The first of these is Collado, in 1642, who has given the ranges of a falconet, carrying a three-pound shot, to every point of the gunner's quadrant, each point being the 12th part, or 7 degrees and a half. But from his numbers it is manifest that the piece was not charged with its usual allotment of powder.

It is extraordinary that before Mr. Robins, there were but four authors who had treated experimentally on gunnery, and those to little purpose; but the treatise of Mr. Robins is still regarded as the foundation of the science.

The first thing considered by him, and which is indeed the foundation of all other particulars relating to gunnery, is the explosive force of gunpowder. The intensity of this force Mr. Robins ascertained in different ways. One of these is by firing the powder in the air, thus: A small quantity of the powder is placed in the upper part of a glass tube, and the lower part of the tube is immersed in water, the water being made to rise so near the top, that only a small portion of air is left in that part where the powder is placed; in this situation the communication between the upper part of the tube and

the external air being closed, the powder is fired by means of a burning-glass, or otherwise; the water descends upon the explosion, and stands lower in the tube than before, by a space proportioned to the quantity of powder fired. Another was by firing the powder in vacuo, viz. in an exhausted receiver, by dropping the grains of powder upon a hot iron excluded in the receiver. For the result of these experiments, see GUNPOWDER.

Having determined the force of the gunpowder, or intensity of the agent by which the projectile is to be urged, Mr. Robins next determined the effects it will produce, or the velocity with which it will impel a shot of a given weight from a piece of ordnance of given dimensions; which is a problem strictly limited, and perfectly soluble by mathematical rules, and is in general this: Given the first force, and the law of its variation, to determine the velocity with which it will impel a given body in passing through a given space, which is the length of the bore of the gun.

In the solution of this problem, Mr. Robins assumes these two postulates, viz. 1. That the action of the powder on the bullet ceases as soon as the bullet is out of the piece; and 2d. That all the powder of the charge is fired and converted into elastic fluid before the bullet is sensibly moved from its place: assumptions which for good reasons are found to be in many cases very near the truth. It is to be noted also, that the law by which the force of the elastic fluid varies, is this; viz. that its intensity is directly as its density, or reciprocally proportional to the space it occupies, being so much the stronger as the space is less; a principle well known, and common to all elastic fluids. Upon these principles then Mr. Robins resolves this problem, by means of the 39th proposition of Newton's *Principia*, in a direct way, and the result is equivalent to this theorem, where the quantities are expressed by algebraic symbols; viz. the velocity of the ball

$$v = 27130 \sqrt{\frac{10a}{cd} \times \log. \frac{b}{a}}.$$

$$\text{or} = 100 \sqrt{\frac{223ad^2}{w} \times \log. \frac{b}{a}}; \text{ whence}$$

v is the velocity of the ball,

a the length of the charge of powder,

b the whole length of the bore,

c the spec. grav. of the ball, or wt. of a cubic foot of the same matter in ounces,

d the diam. of the bore,

w the wt. of the ball in ounces.

For example, Suppose $a = 2\frac{1}{2}$ inc., $b = 45$ inc., $c = 11345$ oz. for a ball of lead. and $d = \frac{3}{4}$ inc.;

$$\text{then } v = 27130 \sqrt{\frac{7}{2269} \times \log. \frac{120}{7}} = 1674 \text{ feet per second, the velocity of the ball.}$$

Or, if the wt. of the bullet be $w = 1\frac{2}{3}$ oz. =

$$\frac{29}{20} \text{ oz. Then } v = 100 \sqrt{\frac{1115 \times 189}{29 \times 32} \times \log. \frac{120}{7}} = 1674 \text{ feet, as before.}$$

"Having in this proposition," says Mr. Robins, "shewn how the velocity, which any bullet acquires from the force of powder, may be computed upon the principles of the theory laid down in the preceding propositions; we shall next shew, that the actual velocities, with which bullets of different magnitudes are impelled from different pieces,

with different quantities of powder, are really the same with the velocities assigned by these computations; and consequently, that this theory of the force of powder, here delivered, does unquestionably ascertain the true action and modification of this enormous power.

"But in order to compare the velocities communicated to bullets by the explosion, with the velocities resulting from the theory by computation, it is necessary that the actual velocities with which bullets move, should be capable of being discovered, which yet is impossible to be done by any methods hitherto made public. The only means hitherto practised by others for that purpose, have been either by observing the time of the flight of the shot through a given space; or by measuring the range of the shot at a given elevation, and thence computing, on the parabolic hypothesis, what velocity would produce this range. The first method labours under this insurmountable difficulty, that the velocities of these bodies are often so swift, and consequently the time observed is so short, that an imperceptible error in that time may occasion an error in the velocity thus found, of 2, 3, 4, 5, or 600 feet in a second. The other method is so fallacious, from the resistance of the air (to which inequality the first is also liable), that the velocities thus assigned may not be perhaps the tenth part of the actual velocities sought.

"To remedy then these inconveniences, I have invented a new method of finding the real velocities of bullets of all kinds; and this to such a degree of exactness (which may be augmented too at pleasure), that in a bullet moving with a velocity of 1700 feet in 1", the error in the estimation of it need never amount to its 500th part; and this without any extraordinary nicety in the construction of the machine."

Mr. Robins then gives an account of the machine by which he measures the velocities of the balls, which machine is simply this; viz. a pendulous block of wood suspended freely by a horizontal axis, against which block are to be fired the balls whose velocities are to be determined.

"This instrument thus fitted, if the weight of the pendulum is known, and likewise the respective distances of its centre of gravity, and of its centre of oscillation, from its axis of suspension, it will thence be known what motion will be communicated to this pendulum by the percussion of a body of a known weight moving with a known degree of celerity, and striking it in a given point; that is, if the pendulum is supposed at rest before the percussion, it will be known what vibration it ought to make in consequence of such a determined blow; and, on the contrary, if the pendulum, being at rest, is struck by a body of a known weight, and the vibration which the pendulum makes after the blow is known, the velocity of the striking body may thence be determined.

"Hence then, if a bullet of a known weight strikes the pendulum, and the vibration which the pendulum makes in consequence of the stroke is ascertained, the velocity with which the ball moved is thence to be known."

Mr. Robins then explains his method of computing velocities from experiments with this machine; which method is rather troublesome and perplexed, as well as the rules of Euler and Antoni, who followed him in

this business; but a much simpler rule is given in Dr. Hutton's Tracts, vol. i. p. 119, where the experiments are explained at full length, and this rule is expressed by either of the two following formulas:

$$v = 5.6727cg \times \frac{p+b}{bir} \sqrt{o} = 614.58cg \times \frac{p+b}{birn},$$

the velocity; where v denotes the velocity of the ball when it strikes the pendulum, p the weight of the pendulum, b the weight of the ball, c the chord of the arc described by the vibration to the radius r , g the distance below the axis of motion to the centre of gravity, o the distance to the centre of oscillation, i the distance to the point of impact, and n the number of oscillations the pendulum will perform in one minute, when made to oscillate in small arcs. The latter of these two theorems is much the easiest, both because it is free of radicals, and because the value of the radical $\sqrt{o}$, in the former, is to be first computed from the number x , or number of oscillations the pendulum is observed to make.

Soon after the first publication of Robins's *New Principles of Gunnery*, in 1742, the learned in several other nations, treading in his steps, repeated and farther extended the same subject, sometimes varying and enlarging the machinery; particularly Euler in Germany, D'Antoni in Italy, and Messrs. D'Arcy and Le Roy in France: but most of these, like Mr. Robins, with small firearms, such as muskets and fusils.

But in the year 1775, in conjunction with several able officers of the Royal Artillery, and other ingenious gentlemen, Dr. Hutton undertook a course of experiments with the ballistic pendulum, in which the machinery was extended to cannon-shot of 1, 2, and 3 pounds weight. An account of these experiments was published in the *Philos. Trans.* for 1778, "and for which," says the Dr., "the Royal Society honoured me with the prize of the gold medal. These were the only experiments that I know of which had been made with cannon-balls for this purpose, although the conclusions to be deduced from such, are of the greatest importance to those parts of natural philosophy which are dependant on the effects of fired gunpowder; nor do I know of any other practical method of ascertaining the initial velocities within any tolerable degree of the truth. The knowledge of this velocity is of the utmost consequence in gunnery; by means of it, together with the law of the resistance of the medium, every thing is determinable relative to that business; for, besides its being an excellent method of trying the strength of different sorts of powder, it gives us the law relative to the different quantities of powder, to the different weights of shot, and to the different lengths and sizes of guns. Besides these, there does not seem to be any thing wanting to answer any inquiry that can be made concerning the flight and ranges of shot, except the effects arising from the resistance of the medium. In these experiments the weights of the pendulums employed were from 300 to near 600 pounds." In that paper is described the method of constructing the machinery, of finding the centres of gravity and oscillation of the pendulum, and of making the experiments, which are all set down in the form of a journal, with all the minute and concomitant circumstances; as also the investigation

of the new and easy rule, set down just above, for computing the velocity of the ball from the experiments. The charges of powder were varied from 2 to 8 ounces, and the shot from 1 to near 3 pounds. And from the whole were clearly deduced these principal inferences: viz.

"1. First, That gunpowder fires almost instantaneously. 2. That the velocities communicated to balls or shot, of the same weight, by different quantities of powder, are nearly in the subduplicate ratio of those quantities; a small variation, in defect, taking place when the quantities of powder became great. 3. And when shot of different weights are employed, with the same quantity of powder, the velocities communicated to them are nearly in the reciprocal subduplicate ratio of their weights. 4. So that, universally, shot which are of different weights, and impelled by the firing of different quantities of powder, acquire velocities which are directly as the square roots of the quantities of powder, and inversely as the square roots of the weights of the shot, nearly. 5. It would therefore be a great improvement in artillery, to make use of shot of a long form, or of heavier matter; for thus the momentum of a shot, when fired with the same weight of powder, would be increased in the ratio of the square root of the weight of the shot. 6. It would also be an improvement to diminish the windage; for by so doing, one-third or more of the quantity of powder might be saved. 7. When the improvements mentioned in the last two articles are considered as both taking place, it is evident that about half the quantity of powder might be saved, which is a very considerable object. But important as this saving may be, it seems to be still exceeded by that of the article of the guns; for thus a small gun may be made to have the effect and execution of another of two or three times its size in the present mode, by discharging a shot of two or three times the weight of its natural ball or round shot. And thus a small ship might discharge shot as heavy as those of the greatest now made use of.

"Finally, as the above experiments exhibit the regulations with regard to the weights of powder and balls, when fired from the same piece of ordnance, &c.; so by making similar experiments with a gun, varied in its length, by cutting off from it a certain part before each course of experiments, the effects and general rules for the different lengths of guns may be certainly determined by them. In short, the principles on which these experiments were made, are so fruitful in consequences, that, in conjunction with the effects resulting from the resistance of the medium, they seem to be sufficient for answering all the enquiries of the speculative philosopher, as well as those of the practical artillerist."

GUNPOWDER, a composition of nitre, sulphur, and charcoal, mixed together, and usually granulated.

It appears that Roger Bacon knew of gunpowder. He tells us, in his *Treatise De Secretis Operibus Artis & Naturæ, & de Nullitate Magiæ*, cap. 6, which is supposed by some to have been published at Oxford in 1216, "that from saltpetre and other ingredients, we are able to make a fire that shall burn at what distance we please." And Dr. Plott, in his *History of Oxfordshire*, p. 236,

assures us that these "other ingredients" were explained in a MS. copy of the same treatise, in the hands of Dr. G. Langbain, and seen by Dr. Wallis, to be sulphur and wood-coal."

As to the preparation of gunpowder, there are various compositions of it, with respect to the proportions of the three ingredients, to be met with in pyrotechnical writings; but the process of making it up is much the same in all.

For some time after the invention of artillery, gunpowder was of a much weaker composition than that now in use. But when guns of modern structure were introduced, gunpowder of the same composition as the present came also into use. In the time of Tartaglia the cannon-powder was made of 4 parts of nitre, one of sulphur, and one of charcoal: and the musket-powder of 48 parts of nitre, 7 parts of sulphur, and 8 parts of charcoal; or of 18 parts of nitre, 2 parts of sulphur, and 3 parts of charcoal; the modern composition is,

| |
|----------------|
| 76 parts nitre |
| 15 charcoal |
| 9 sulphur |
| — |
| 100. |

These ingredients are first reduced to a fine powder separately, then mixed intimately, and formed into a thick paste with water. After this has dried a little, it is placed upon a kind of sieve full of small holes, through which it is forced. By that process it is divided into grains, the size of which depends upon the size of the holes through which they have been squeezed. The powder, when dry, is put into barrels, which are made to turn round on their axes. By this motion the grains of gunpowder rub against each other, their asperities are worn off, and their surfaces are made smooth. The powder is then said to be glazed.

Gunpowder, as is well known, explodes violently when a red heat is applied to it. This combustion takes place even in a vacuum; a vast quantity of gas is emitted, the sudden production of which is the cause of all the violent effects which this substance produces. Their combustion is evidently owing to the decomposition of the nitre by the charcoal and sulphur. The products are carbonic acid gas, azotic gas, sulphurous acid gas, and probably sulphureted hydrogen. Mr. Cruikshank has ascertained that no perceptible quantity of water is formed. What remains after the combustion is potass combined with a small portion of carbonic acid, sulphat of potass, a very small proportion of sulphuret of potass, and unconsumed charcoal. This mixture soon attracts moisture, and the sulphuret which it contains enables it to act strongly on metallic bodies.

To make gunpowder duly, regard is to be had to the purity or goodness of the ingredients, as well as the proportions of them; for the strength of the powder depends much on that circumstance, and also on the due working or mixing of them together.

To purify the nitre, by taking away the fixt or common salt, and earthy part. Dissolve it in a quantity of hot water over the fire; then filtrate it through a flannel bag, into an open vessel, and set it aside to cool, and to crystallize. These crystals may in like manner be dissolved and crystallized again; and so on, till they become quite pure

and white. Then put the crystals into a dry kettle over a moderate fire, which gradually increase till it begins to smoke, evaporate, lose its humidity, and grow very white: it must be kept continually stirring with a ladle, lest it should return to its former figure, by which its greasiness would be taken away; after that, so much water is to be poured into the kettle as will cover the nitre; and when it is dissolved, and reduced to the consistency of a thick liquor, it must be continually stirred with a ladle till all the moisture is again evaporated, and it is reduced to a dry and white meal.

The like regard is to be had to the sulphur; choosing that which is in large lumps, clear and perfectly yellow; not very hard, nor compact, but porous; not yet too much shining; and if, when set on fire, it freely burns all away, it is a sign of its goodness; so likewise, if it is pressed between the two iron plates that are hot enough to make it run, and in the running appear yellow, and that which remains of a reddish colour, it is then fit for the purpose. But in case it is foul, it may be purified in this manner; melt the sulphur in a large iron ladle or pot, over a very gentle coal-fire, well kindled, but not flaming; then scum off all that rises on the top, and swims upon the sulphur; take it presently after from the fire, and strain it through a double linen cloth, letting it pass leisurely; so will it be pure, the gross matter remaining behind in the cloth.

For the charcoal, the third ingredient, such should be chosen as is large, clear, and free from knots, well burnt, and cleaving. The charcoal of light woods is mostly preferred, as of willow, and that of the branches or twigs of a moderate thickness, as of an inch or two in diameter. Dogwood is now much esteemed for this purpose. And a method of charring the wood in a large iron cylinder has lately been recommended, and indeed proved, as yielding better charcoal than formerly.

The charcoal not only concurs with the sulphur in supplying the inflammable matter, which causes the detonation of the nitre, but also greatly adds to the explosive power of it by the quantity of carbonic acid gas, expelled during its combustion.

These three ingredients, in their purest state, being procured, long experience has shewn that they are then to be mixed together in the proportion before-mentioned, to have the best effect.

But it is not the due proportion of the materials only, which is necessary to the making of good powder; another circumstance, not less essential, is the mixing them well together; if this is not effectually done, some parts of the composition will have too much nitre in them, and others too little; and in either case there will be a defect of strength in the powder.

After the materials have been reduced to fine dust, they are mixed together, and moistened with water, or vinegar, or urine, or spirit of wine, &c. and then beaten together with wooden pestles for 24 hours, either by hand, or by mills, and afterwards pressed into a hard, firm, and solid cake. When dry, it is grained or corned, which is done by breaking the cake of powder into small pieces, and so running it through a sieve; by which

means the grains may have any size given them, according to the nature of the sieve employed, either finer or coarser; and thus also the dust is separated from the grains, and again mixed with other manufacturing powder, or worked up into cakes again.

Powder is smoothed, or glazed, as it is called, for small arms, by the following operation: a hollow cylinder or cask is mounted on an axis, turned by a wheel; this cask is half-filled with powder, and turned for six hours; and thus by the mutual friction of the grains of powder it is smoothed, or glazed. The fine mealy part, thus separated or worn off from the rest, is again granulated.

The nature, effects, &c. of powder. When the powder is separated as above, if the least spark is struck upon it from a steel and flint, the whole will immediately inflame, and burst out with extreme violence. The effect is not hard to account for: the charcoal part of the grain upon which the spark falls, catching fire like tinder, the sulphur and nitre are readily melted, and the former also breaks into flame; the contiguous grains at the same time undergoing the same fate.

The explosion of gunpowder therefore arises from the violent action, by which all the mixture being quickly and vehemently heated, is rarefied and converted into gas and vapour; which vapour, by the violence of that action becoming so hot as to shine, appears in the form of a flame.

To understand the force of gunpowder, it must be considered that, whether it is fired in a vacuum or in air, it produces by its explosion permanently elastic fluids. It also appears from experiment, that the elasticity or pressure of the fluids produced by the firing of gunpowder is, *ceteris paribus*, directly as its density.

To determine the elasticity and quantity of the elastic fluids produced from the explosion of a given quantity of gunpowder, Mr. Robins premises, that the elasticity of the fluids increases by heat, and diminishes by cold, in the same manner as that of the air; and that the density of this fluid, and consequently its weight, are the same with the weight of an equal bulk of air, having the same elasticity and the same temperature. From these principles, and from the experiments by which they are established, he concludes that the fluid produced by the firing of gunpowder is nearly three-tenths of the weight of the generating powder itself; and that the volume or bulk of this air or fluid, when expanded to the rarity of common atmospheric air, is about 244 times the bulk of the powder.

Hence it appears, that any quantity of powder fired in any confined space, which it adequately fills, exerts at the instant of its explosion against the sides of the vessel containing it, and the bodies it impels before it, a force at least 244 times greater than the elasticity of common air, or, which is the same thing, than the pressure of the atmosphere; and this without considering the great addition arising from the violent degree of heat with which it is endued at that time; the quantity of which augmentation is the next head of Mr. Robins's enquiry. He determines that the elasticity of the air is augmented in a proportion somewhat greater than that of 4 to 1, when heated to

the extremest heat of red-hot iron; and supposing that the flame of fired gunpowder is not of a less degree of heat, increasing the former number a little more than four times, makes nearly 1000; which shews that the elasticity of the flame, at the moment of explosion, is about 1000 times stronger than the elasticity of common air, or than the pressure of the atmosphere. But, from the height of the barometer, it is known that the pressure of the atmosphere upon every square inch, is on a medium $14\frac{1}{2}$ lb.; and therefore 1000 times this, or 14750 lb. is the force or pressure of the flame of gunpowder, at the moment of explosion, upon a square inch, which is very nearly equivalent to six tons and a half.

This great force, however, diminishes as the fluid dilates itself, and in that proportion, viz. in proportion to the space it occupies, it being only half the strength when it occupies a double space, one-third the strength when triple the space, and so on.

Mr. Robins farther supposes the degree of heat above-mentioned to be a kind of medium heat; but that in the case of large quantities of powder the heat will be higher, and in very small quantities lower; and that therefore in the former case the force will be somewhat more, and in the latter somewhat less, than 1000 times the force of the atmosphere.

He farther found that the strength of powder is the same in all variations in the density of the atmosphere, but that the moisture of the air has a great effect upon it; for the same quantity which in a dry season would discharge a bullet with a velocity of 1700 feet in one second, will not in damp weather give it a velocity of more than 12 or 1300 feet in a second, or even less, if the powder is bad; and negligently kept. Farther, as there is a certain quantity of water which, when mixed with powder, will prevent its firing at all, it cannot be doubted that every degree of moisture must abate the violence of the explosion; and hence the effects of damp powder are not difficult to account for.

It is to be observed, that the moisture imbibed by powder does not render it less active when dried again. Indeed, if powder is exposed to very great damps without any caution, or when common salt abounds in it, as often happens through negligence in refining the nitre, in such cases the moisture it imbibes may perhaps be sufficient to dissolve some part of the nitre; which is a permanent damage that no drying can retrieve. But when tolerable care is taken in preserving powder, and the nitre it is composed of has been well purged from common salt, it will retain its force for a long time; and it is said that powder has been known to have been preserved for 50 years without any apparent damage from its age.

The velocity of expansion of the flame of gunpowder, when fired in a piece of artillery, without either bullet or other body before it, is prodigiously great, viz. 7000 feet per second, or upwards, as appears from the experiments of Mr. Robins. But Mr. Bernoulli and Mr. Euler suspect it is still much greater. Perhaps, indeed, it may not be less, at the moment of explosion, than four times as much.

It is this prodigious celerity of expansion of the flame of fired gunpowder, which is its

peculiar excellence, and the circumstance in which it so eminently surpasses all other inventions, either ancient or modern; for as to the momentum of these projectiles only, many of the warlike machines of the ancients produced in this a degree far surpassing that of our heaviest cannon-shot or shells; but the great celerity given to these bodies cannot be in the least approached by any other means but the flame of powder. The best means of proving gunpowder is that of the pendulum, already described under the article GUNNERY.

To recover damaged powder. The method of the powder-merchants is this: they put part of the powder on a sail-cloth, to which they add an equal weight of what is really good; then with a shovel they mingle it well together, dry it in the sun, and barrel it up, keeping it in a dry and proper place.

Others again, if it is very bad, restore it by moistening it with vinegar, water, urine, or brandy; then they beat it fine, sift it, and to every pound of powder add an ounce, or an ounce and a half, or two ounces (according as it is decayed), of melted nitre; and afterwards these ingredients are to be moistened and well mixed, so that no particular substance may be discerned: which may be known by cutting the mass, and then they granulate it as usual.

In case the powder is quite spoiled, the only thing to be done is to extract the saltpetre with water, in the usual way, by boiling, filtrating, evaporating, and crystallizing; and then, with fresh sulphur and charcoal, to make it up afresh.

GUNPOWDER and combustibles, laws concerning. No person shall make gunpowder but in the regular manufactories established at the time of making the stat. 12 Geo. III. c. 61. or licensed by the sessions, pursuant to certain provisions, under forfeiture of the gunpowder, and 2s. per lb. nor are pestle-mills to be used under a similar penalty.

Only 40 lbs. of powder to be made at one time under one pair of stones, except Battle-powder, made at Battle and elsewhere in Sussex.

Not more than 40 cwt. to be dried at one time in one stove; and the quantity only required for immediate use to be kept in or near the place of making, except in brick or stone magazines, 50 yards at least from the mill.

Not more than 25 barrels to be carried in any land carriage, nor more than 200 barrels by water, unless going by sea or coastwise, each barrel not to contain more than 100 lbs.

No dealer to keep more than 200 lbs. of powder, nor any person not a dealer, more than 50 lbs. in the cities of London or Westminster, or within three miles thereof, or within any other city, borough, or market-town, or one mile thereof, or within two miles of the king's palaces or magazines, or half a mile of any parish-church, on pain of forfeiture; and 2s. per lb. except in licensed mills, or to the amount of 300 lbs. for the use of collieries, within 200 yards of them.

GUN-SMITHERY, the business of a gunsmith, or the art of making fire-arms of the smaller sort, as muskets, fowling-pieces, pistols, &c. The principal part of these instruments is the barrel, which ought to have the following properties: 1. Lightness, that it

may incommode the person who carries it as little as possible. 2. Sufficient strength, and other properties requisite to prevent its bursting by a discharge. 3. It ought to be constructed in such a manner as not to recoil with violence. And, 4. it ought to be of sufficient length to carry the shot to as great a distance as the force of the powder employed is capable of doing.

The manufacture of fire-arms is now carried to such a degree of perfection by different European nations, that it may perhaps be justly doubted whether any farther improvement in the requisites just mentioned can be made. For the materials the softest iron that can be procured is to be employed. The best in this country are formed of stubs, as they are called, or old horse-shoe nails; which are procured by gun-smiths from farriers, and from poor people who subsist by picking them up on the great roads leading to London. These are sold at about ten shillings per cwt. and 28 pounds are requisite to form a single musket-barrel. The method of manufacturing them from this material is as follows: A hoop of about an inch broad, and six or seven inches diameter, is placed in a perpendicular situation, and the stubs, previously well cleaned, piled up in it with their heads outermost on each side, till the hoop is quite filled and wedged tight with them. The whole then resembles a rough circular cake of iron; which being heated to a white heat, and then strongly hammered, coalesces into one solid lump. The hoop is now removed, and the heatings and hammerings repeated till the iron is rendered very tough and close in the grain; when it is drawn out into pieces of about 24 inches in length, half an inch or more in breadth, and half an inch in thickness. It is, however, not easy to conceive how old stubs can be procured sufficient to supply iron for the number of barrels which go under this denomination. Nor do we, upon any principles of science, see any farther advantage to be derived from this manufacture, than that nail-iron is generally the best of iron, and well hammered.

Four of the pieces, prepared as has been described, are required for one barrel; but in the ordinary way a single bar of the best soft iron is employed. The workmen begin with hammering out this into the form of a flat ruler, having its length and breadth proportioned to the dimensions of the intended barrel. By repeated heating and hammering this plate is turned round a tempered iron-rod called a mandril, the diameter of which is considerably smaller than the intended bore of the barrel. One of the edges of the plate being laid over the other about half an inch, the whole is heated and welded by two or three inches at a time, hammering it briskly, but with moderate strokes, upon an anvil which has a number of semicircular furrows in it, adapted to the barrels of different sizes. Every time the barrel is withdrawn from the fire, the workman strikes it gently against the anvil once or twice in an horizontal direction. By this operation the particles of the metal are more perfectly consolidated, and every appearance of a seam in the barrel is obliterated. The mandril being then again introduced into the cavity of the barrel, the latter is very strongly hammered upon it in one of the semicircular hollows of the anvil, by small portions at a time; the heatings and

hammerings being repeated until the whole barrel has undergone the operation, and its parts rendered as perfectly continuous as if they had been formed out of a solid piece. To effect this completely, three welding heats are necessary when the very best iron is made use of, and a greater number for the coarser kinds. The French workmen imagine that by giving the barrel, while in the fire, slight horizontal strokes with the hammer, so as to communicate a vibratory motion to the iron, those particles are thrown off which are in a state of fusion, and cannot easily be converted into malleable iron: but considering the great number of operations already described which the metal has undergone, we can scarcely suppose this to be of much consequence.

The next operation in forming the barrels is the boring of them, which is done in the following manner: Two beams of oak, each about six inches in diameter, and six or seven feet long, are placed horizontally, and parallel to one another; having each of their extremities mortised upon a strong upright piece about three feet high, and firmly fixed. A space of three or four inches is left between the horizontal pieces, in which a piece of wood is made to slide by having at either end a tenon let into a groove which runs on the inside of each beam throughout its whole length. Through this sliding piece a strong pin or bolt of iron is driven or screwed in a perpendicular direction, having at its upper end a round hole large enough to admit the breech of the barrel, which is secured in it by means of a piece of iron that serves as a wedge, and a vertical screw passing through the upper part of the hole. A chain is fastened to a staple in one side of the sliding piece which runs between the two horizontal beams; and passing over a pulley at one end of the machine, has a weight hooked on to it. An upright piece of timber is fixed above this pulley and between the ends of the beams, having its upper end perforated by the axis of an iron crank furnished with a square socket; the other axis being supported by the wall, or by a strong post, and loaded with a heavy wheel of cast iron to give it force. The axes of this crank are in a line with the hole in the bolt already mentioned. The borer being then fixed into the socket of the crank, has its other end, previously well oiled, introduced into the barrel, whose breech part is made fast in the hole of the bolt: the chain is then carried over the pulley, and the weight hooked on; the crank being then turned with the hand, the barrel advances as the borer cuts its way, till it has passed through the whole length. The boring bit consists of an iron-rod somewhat longer than the barrel, one end of which fits the socket of the crank; the other is adapted to a cylindrical piece of tempered steel, about an inch and a half in length, having its surface cut after the manner of a perpetual screw, with five or six threads, the obliquity of which is very small. The breadth of the furrows is the same with that of the threads, and their depth sufficient to let the metal cut by the threads pass through them easily. Thus the bit gets a strong hold of the metal; and the threads, being sharp at the edges, scoop out and remove all the inequalities and roughness from the inside of the barrel, and render the cavity smooth and equal throughout. A number of

bits, each a little larger than the former, are afterwards successively passed through the barrel in the same way, until the bore has acquired the magnitude intended. By this operation the barrel is very much heated, especially the first time the borer is passed through it, by which means it is apt to warp. To prevent this in some measure, the barrel is covered with a cloth kept constantly wetted, which not only preserves the barrel from an excess of heat, but likewise preserves the temper of the bit from being destroyed. The borer itself must also be withdrawn from time to time; both to clean it from the shavings of the metal and to oil it, or repair any damages it may have sustained. Every time a fresh bit has been passed through the barrel, the latter must be carefully examined, to see if it has warped; and likewise if there are any spots, by the workmen called *blacks*, on its inside. When warped, it must be straightened on the anvil, for which a few slight strokes on the convex parts will be sufficient; and this is termed *setting-up* the barrel. When black spots are perceived, the corresponding part on the outside must be marked, and driven in by gentle strokes with the hammer, when they will be completely removed by passing the borer another time through the piece.

The equality of the bore is of the utmost consequence to the perfection of a barrel; inasmuch that the greatest possible accuracy in every other respect will not make amends for any deficiency in this. The method used by gunsmiths to ascertain this is by a cylindrical plug of tempered steel highly polished, about an inch in length, and fitting the bore exactly. This is screwed upon the end of an iron-rod, and introduced into the cavity of the barrel, where it is moved backwards and forwards; and the places where it passes with difficulty being marked, the boring bit is repeatedly passed until it moves with equal ease through every part. Any person who wishes to know the merit of his piece in this respect, may do it with tolerable accuracy by means of a plug of lead cast on a rod of iron; or even by a musket-ball filed exactly to the bore, and pushed through the barrel by a ramrod; taking care, however, not to use much force lest the ball be flattened, and its passage thus rendered difficult.

The first tool employed in forming the breech-screw is a plug of tempered steel, somewhat conical, with the threads of a male screw upon its surface, and by the workmen termed a *screw-tap*. This being introduced into the barrel, and worked from left to right and back again, until it has marked out the first four threads of the screw, another less conical tap is introduced; and when this has carried the impression of the screw as far as it is intended to go, a third one, nearly cylindrical, is made use of, scarcely differing from the plug of the breech intended to fill the screw thus formed in the barrel. The plug itself has its screw formed by means of a screw-plate of tempered steel, with several female screws, corresponding with the taps employed for forming that in the barrel. Seven or eight threads are a sufficient length for a plug: they ought to be neat and sharp, so as completely to fill the turns made in the barrel by the tap. The breech-plug is then to be case-hardened, or to have its surface converted into steel, by covering it with shav-

ings of horn, or the parings of the hoofs of horses, and keeping it for some time red-hot after which it is plunged in cold water.

Thus the common barrels, for the purpose especially of sporting, are made; but there are some other methods of manufacture, by which the barrels are made to differ in some respects from those just described, and are thought to be considerably improved. One kind of these are called *twisted* barrels; and by the English workmen are formed out of the plates made of *stubs*, as above described. Four of these, of the size already mentioned, are requisite to make one barrel. One of them, heated red-hot for five or six inches, is turned like a corkscrew, by means of the hammer and anvil; the remaining parts being treated successively in the same manner until the whole is turned into a spiral, forming a tube, the diameter of which corresponds with the bore of the intended barrel. Four are generally sufficient to form a barrel of the ordinary length, *i. e.* from 32 to 38 inches; and the two which form the breech or strongest part, called the *reinforced part*, are considerably thicker than those which form the muzzle, or fore part of the barrel. One of these tubes is then welded to a part of an old barrel to serve as an handle; after which the turns of the spiral are united by heating the tube two or three inches at a time to a bright white heat, and striking the end of it several times against the anvil in a horizontal direction with considerable strength, which is called *jumping the barrel*; and the heats given for this purpose are called *jumping heats*. The next step is to introduce a mandril into the cavity, and to hammer the heated portion lightly, in order to flatten the ridges or burrs raised by the jumping at the place where the spirals are joined. As soon as one piece is jumped throughout its whole length, another is welded to it, and treated in the same manner, until the four pieces are united, when the part of the old barrel is cut off, as being no longer of any use. The welding is repeated three times at least, and is performed exactly in the same manner as directed for plain barrels; and the piece may afterwards be finished according to the directions already given.

The advantages of twisted barrels are, after all, somewhat problematical; where there is so much of welding, and that in a spiral form, the welding is more likely to be done in a careless manner, or with some imperfection in some part, than when it is a plain and obvious business: nor have we observed that twisted barrels are less liable to burst than plain ones, where the latter have been well and carefully forged.

The Spanish barrels have been long held in great estimation; yet as the Spanish iron is universally allowed to be unusually good, it is probable that the superiority of their barrels is owing more to the goodness of the materials than to the skill of the workmen. It must be observed, however, that instead of making the plates overlap a little in the place where they join, they give one of them a complete turn; so that every Spanish barrel may be said to be double throughout its whole length. The different portions of the iron are also forged in such a manner, that the grain of the iron is disposed in a spiral manner; whence it has the same effect with a ribbon or twisted barrel. The outside is

finished by turning them in a lathe; whence probably they are always less elegantly wrought than the French and English pieces. The great value put upon them is also thought to be more owing to fancy than to any real good qualities they possess. Formerly they were made from three to three feet and a half long; their bore being such as to admit a bullet from 22 to 24 in the pound, and their weight from three to three pounds and a half. The reinforced part extends two-fifths of the length; and at 10 or 12 inches from the breech is placed a sight, such as is usually put upon rifle-barrels, or those intended only for ball. According to Espinas, arquebuss-bearer to Philip IV. the weight of a Spanish barrel ought to be four pounds and a half when the length is 42 inches; but both in weight and length they are now much reduced, and seldom exceed the dimensions already mentioned.

The principal imperfections to which gun-barrels are liable, are the chink, crack, and flaw. The first is a small rent in the direction of the length of the barrel; the second across it; and the third is a kind of scale or small plate adhering to the barrel by a narrow base, from which it spreads out like the head of a nail from its shank, and, when separated, leaves a pit or hollow in the metal. The chink or flaw are of much worse consequence than the crack in fire-arms, the force of the powder being exerted more upon the circumference than the length of the barrel. The flaw is much more frequent than the chink, the latter scarcely ever occurring but in plain barrels formed out of a single plate of iron, and then only when the metal is deficient in quality. When flaws happen on the outside they are of no great consequence; but in the inside they are apt to lodge moisture and foulness which corrode the iron, and thus the cavity enlarges continually till the piece bursts. This accident, however, may arise from many other causes besides the defect of the barrel itself. The best pieces will burst when the ball is not sufficiently rammed home, so that a space is left between it and the powder. A very small windage or passage for the inflamed powder between the sides of the barrel and ball will be sufficient to prevent the accident; but if the ball has been forcibly driven down with an iron ramrod, so as to fill up the cavity of the barrel very exactly, the piece will almost certainly burst, if only a very small space is left between it and the powder; and the greater the space is, the more certainly does the event take place. A piece will frequently burst from having its mouth stopped up with earth or snow; which accident sometimes happens to sportsmen in leaping a ditch, in which they have assisted themselves with their fowling-piece, putting the mouth of it to the ground; and when this did not happen, it is only to be accounted for from the stoppage being extremely slight. For the same reason a musket will certainly burst if it is fired with the muzzle immersed only a very little way in water. It will also burst from an overcharge; but when such an accident happens in other circumstances, it is most probably to be attributed to a defect in the workmanship, or in the iron itself. These defects are principally an imperfection in the welding, a deep flaw having taken place, or an inequality in the bore; which last is the most common of

any, especially in the low-priced barrels. The reason of a barrel's bursting from an inequality in the bore is, that the elastic fluid, set loose by the inflammation of the powder, and endeavouring to expand itself in every direction, being repelled by the stronger parts, acts with additional force against the weaker ones, and frequently bursts through them, which it would not have done had the sides been equally thick and strong throughout. With regard to defects arising from the bad quality of the iron, it is impossible to say any thing certain. As the choice of the materials depends entirely on the gunsmith, the only way to be assured of having a barrel made of proper metal is to purchase it from an artist of known reputation, and to give a liberal price for the piece.

The recoil of a piece becomes an object of importance only when it is very great; for every piece recoils in some degree when it is discharged. The most frequent cause of an excessive recoil is an inequality in the bore of the barrel; and by this it will be occasioned even when the inequality is too small to be perceived by the eye. The explanation of this upon mechanical principles indeed is not very easy: for as it is an invariable law, that action and reaction are equal to one another, we should be apt to suppose that every time a piece is discharged it should recoil with the whole difference between the velocity of the bullet and that of the inflamed powder. The cause to which too great a recoil in muskets has been usually attributed, is the placing of the touch-hole at some distance from the breech-plug; so that the powder is fired about the middle, or towards its fore part, rather than at its base. To avoid this some artists form a groove or channel in the breech-plug as deep as the second or third turn of the screw; the touch-hole opening into this channel, and thus firing the powder at its very lowest part. It appears, however, from a number of experiments made upon this subject by M. le Clerc, that it made very little difference with regard to the recoil, whether the touch-hole was close to the breech, or an inch distant from it. The only circumstance to be attended to with respect to its situation therefore is, that it be not quite close to the breech-plug; as in such a case it is found to be more apt to be choked up than when placed about a quarter of an inch from it.

The only other circumstance now to be determined with regard to musket-barrels is their proper length. Formerly it was supposed that the longer they were made, the greater would be the distance to which they carried the shot, and that without any limitation. This opinion continued to prevail till about half a century ago, when it was first proposed as a doubt whether long barrels carried farther than short ones. With regard to cannon, indeed, it had long before this time been known that they might be made too long; and Balthazar Killar, a celebrated cannon-founder in the reign of Louis XIV. was able to account for it. When asked by Mons. Suriry de St. Remy, why the culverin of Nancy, which is 22 feet long, did not carry a ball equally far with a shorter piece, he replied, that "the powder, when inflamed, ought to quit the cavity of the piece in a certain time, in order to exert its whole force upon the bullet; by a longer stay part of the

force is lost; and the same cause may produce an inequality in the shots, by giving a variation to the bullet, so as to destroy its rectilinear course, and throw it to one side or other of the mark." Mr. Robins informs us, that "if a musket-barrel, of the common length and bore, is fired with a leaden bullet and half its weight of powder, and if the same barrel is afterwards shortened one-half, and fired with the same charge, the velocity of the bullet in this shortened barrel will be about one-sixth less than what it was when the barrel was entire; and if, instead of shortening the barrel, it is increased to twice its usual length, when it will be near eight feet long, the velocity of the bullet will not be augmented more than one-eighth part. And the greater the length of the barrel is in proportion to the diameter of the bullet, and the smaller the quantity of powder, the more inconsiderable will these alterations of velocity be." From these considerations it appears, that the advantages gained by long barrels are by no means equivalent to the disadvantages arising from the weight and incumbrance of using them; and from a multitude of experiments it is now apparent, that any one may choose what length he pleases, without any sensible detriment to the range of his piece. The most approved lengths are from 30 to 36 inches.

An opinion has generally prevailed among sportsmen, that by some unknown manœuvre the gunsmith is able to make a piece, loaded with small shot, throw the contents so close together, that even at the distance of 40 or 50 paces the whole will be confined within the breadth of a hat. From such experiments as have been made on this subject, however, it appears, that the closeness or wideness with which a piece throws its shot is liable to innumerable variations from causes which no skill in the gunsmith can possibly reach. So variable are these causes, that there is no possibility of making the same piece throw its shot equally close twice successively. In general, however, the closer the wadding is, the better disposed the shot seems to be to fall within a small compass. In firing with small shot a curious circumstance sometimes occurs, viz. that the grains, instead of being equally distributed over the space they strike, are thrown in clusters of 10, 12, 15, or more; whilst several considerable spaces are left without a grain in them. Sometimes one-third or one-half of the charge will be collected into a cluster of this kind; nay, sometimes, though much more rarely, the whole charge will be collected into one mass, so as to pierce a board near an inch thick at the distance of 40 or 45 paces. Small barrels are said to be more liable to this clustering than large ones; and M. de Marolles informs us, that this is especially the case when the barrels are new, and likewise when they are fresh-washed; though he acknowledges that it did not always happen with the barrels he employed even after they were washed. It is probable, therefore, that the closeness of the shot depends on some circumstance relative to the wadding rather than to the mechanism of the barrel.

GUN-SHOT WOUNDS are attended with much worse consequences than wounds made by sharp instruments; for the parts are more shattered and torn, especially when the shot

falls upon the joints, bones, or any considerable part. See SURGERY.

GUNTER'S CHAIN, the chain in common use for measuring land, according to the true or statute measure; so called from Mr. Gunter, its reputed inventor.

The length of the chain is 66 feet, or 22 yards, or four poles of five yards and a half each; and it is divided into 100 links, of 7.92 inches each.

This chain is the most convenient of any thing for measuring land, because the contents thence computed are so easily turned into acres. The reason of which is, that an acre of land is just equal to 10 square chains, or 10 chains in length and one in breadth, or equal to 100,000 square links. Hence the dimensions being taken in chains, and multiplied together, it gives the content in square chains; which therefore being divided by 10, or a figure cut off for decimals, brings the content to acres: after which the decimals are reduced to roods and perches, by multiplying by 4 and 40. But the better way is to set the dimensions down in links as integers, considering each chain as 100 links; then, having multiplied the dimensions together, producing square links, divide these by 100,000 that is, cut off five places for decimals, the rest are acres, and the decimals are reduced to roods and perches as before.

Ex. Suppose, in measuring a rectangular piece of ground, its length be

795 links,

and its breadth 480 links.

63600

3180

Ac. 3.81600

4

Ro. 3.264

40

Per. 10.560

So the content is 3 acres 3 roods 10 perches.

GUNTER'S LINE, a logarithmic line, usually graduated upon scales, sectors, &c.

It is also called the line of lines, and line of numbers; being only the logarithms graduated upon a ruler, which therefore serves to solve problems instrumentally in the same manner as logarithms do arithmetically. It is usually divided into a hundred parts, every tenth of which is numbered, beginning with 1, and ending with 10; so that if the first great division, marked 1, stand for one-tenth of any integer, the next division, marked 2, will stand for two-tenths; 3, three-tenths, and so on; and the intermediate divisions will, in like manner, represent 100th parts of some integer. If each of the great divisions represent 10 integers, then will the lesser divisions stand for integers; and if the great divisions be supposed each 100, the subdivisions will be each 10.

USE OF GUNTER'S LINE.

1. To find the product of two numbers. From 1 extend the compasses to the multiplier; and the same extent, applied the same way from the multiplicand, will reach to the product. Thus if the product of 4 and 8 be required, extend the compasses from 1 to 4 and that extent laid from 8 the same way, will reach to 32, their product.

2. To divide one number by another. The extent from the divisor to unity will reach from the dividend to the quotient: thus to divide 36 by 4, extend the compasses from 4 to 1, and the same extent will reach from 36 to 9, the quotient sought.

3. To three given numbers, to find a fourth proportional. Suppose the numbers 6, 8, 9; extend the compasses from 6 to 8, and this extent, laid from 9 the same way, will reach to 12, the fourth proportional required.

4. To find a mean proportional between any two given numbers. Suppose 8 and 32: extend the compasses from 8 in the left-hand part of the line, to 32 in the right; then bisecting this distance, its half will reach from 8 forward, or from 32 backward, to 16, the mean proportional sought.

5. To extract the square root of any number. Suppose 25: bisect the distance between 1 on the scale and the point representing 25; then the half of this distance, set off from 1, will give the point representing the root 5. In the same manner the cube root, or that of any higher power, may be found by dividing the distance on the line, between 1 and the given number, into as many equal parts as the index of the power expresses; then one of those parts, set from 1, will find the point representing the root required.

GUNTER'S QUADRANT, one made of wood, brass, &c. containing a kind of stereographic projection of the sphere, on the plane of the equinoctial; the eye being supposed placed in one of the poles.

Besides the use of this quadrant in finding heights and distances, it serves also to find the hour of the day, the sun's azimuth, and other problems of the globe.

GUNTER'S SCALE, usually called by seamen the *Gunter*, is a large plane scale, having various lines upon it, of great use in working the cases or questions in navigation.

This scale is usually two feet long, and about an inch and a half broad, with various lines upon it, both natural and logarithmic, relating to trigonometry, navigation, &c.

On one side are the natural lines, and on the other the artificial or logarithmic ones. The former side is first divided into inches and tenths, and numbered from 1 to 24 inches, running the whole length near one edge. One-half the length of this side consists of two plane diagonal scales, for taking off dimensions to three places of figures. On the other half or foot of this side are contained various lines relating to trigonometry, in the natural numbers, and marked thus, viz.

Rumb, the rumb or points of the compass;

Chord, the line of chords;

Sine, the line of sines;

Tang. the tangents;

S. T. the semitangents; and at the other end of this half are,

Leag. leagues, or equal parts;

Rumb. another line of rumbs;

M. L. miles of longitude;

Chor. another line of chords.

Also in the middle of this foot are *L.* and *P.* two other lines of equal parts. And all these lines on this side of the scale serve for drawing or laying down the figures to the cases in trigonometry and navigation.

On the other side of the scale are the following artificial or logarithmic lines, which

serve for working or resolving those cases, viz.

S. R. the sine rumbs;

T. R. the tangent rumbs;

Numb. line of numbers;

Sine, sines;

V. S. the versed sines;

Tang. the tangents;

Meri. meridional parts;

E. P. equal parts.

GUN-WALE, or GUNNEL, is the uppermost wale of a ship, or that piece of timber which reaches on either side from the quarter-deck to the fore-castle, being the uppermost bend which finishes the upper works of the hull, in that part in which are put the stanchions which support the waste-trees.

GUSSET, in heraldry, is formed by a line drawn from the dexter or sinister chief points, and falling down perpendicularly to the extreme base. The gusset is an abatement of honour, denoting an effeminate person.

GUSTAVIA, a genus of the polyandria order, in the monadelphia class of plants. There is no calyx; the petals very numerous; the berry multilocular; the seeds appendaged. There is one species, a tree of Surinam.

GUTTÆ. See ARCHITECTURE.

GUTTA-SERENA, a disease in which the patient, without any apparent fault in the eye, is entirely deprived of sight. See SURGERY.

GUTTY, in heraldry, a term used when any thing is charged or sprinkled with drops. In blazoning, the colour of the drops is to be named, as gutty of sable, of gules, &c.

GUY, in a ship, is any rope used for keeping off things from bearing or falling against the ship's sides when they are hoisting in. That rope which at one end is made fast to the foremast, and seized to a single block at the pendant of the garnet, is called the guy of the garnet.

GUZES, in heraldry, roundles of a sanguine or murry colour. These, from their bloody hue, are by some supposed to represent wounds.

GYMNANTHES, a genus of the class and order monœcia monadelphia. The male has an ament naked; perianthium and corolla none; stamina pedicles, three-parted or three-forked, anther bearing. The female has an ament or germ pedicelled; corolla none; style trifid; capsule tricoccus, three-celled. There are two species, shrubs of the West Indies.

GYMNETRUS, a genus of fishes, of the order of thoracici. The generic character is, body extremely long, compressed; teeth numerous, subulate; gill membrane, four or five-rayed; anal fin wanting. The most remarkable species are:

1. *Gymnetrus Ascanii*, or Ascanian gymnetrus. This extraordinary fish is a native of the northern seas, and seems to have been first described by professor Ascanius, in his work entitled *Icones rerum Natularium*, &c. The length of the specimen was ten feet, and the diameter, which was equal throughout the whole length, about six inches: the head short, the mouth small, and the eyes rather large: on the upper part of the head, before the commencement of the dorsal fin, were situated 7 or 8 upright naked rays or pro-

cesses, of moderate length: the dorsal fin, which was rather shallow, commenced at a small distance beyond these, and running along the whole length of the back, formed by its continuation the tail-fin: the ventral fins, if they can be said to deserve the name, consisted of a pair of extremely long single rays or processes terminated by a small ovate expanded tip or finny extremity: the gill-covers appeared to consist of five or six radiated laminae: the colour of the whole body was bright silver, with a blueish cast diffused over the upper part of the back: the lateral line was strongly marked, and ran from the gill-covers to the tail, and the sides of the body were marked by several longitudinal double rows of slightly extant, very small dusky specks; the forehead was white; the fins pale brown.

This fish is said to be generally seen either preceding or accompanying the shoals of herrings in the northern seas, for which reason it is popularly known by the title of king of the herrings.

2. *Blochian gymnetrus*. This, which is a native of the Indian seas, and which appears also to be occasionally seen in those of Europe, is described by Dr. Bloch from a drawing communicated by J. Hawkins, Esq. In its general appearance it is much allied to the preceding kind, but appears to be furnished with two pair of ventral processes, which are of considerable length, and terminate in large, dilated, finny extremities, of an oval form: the back-fin is continued as far as the tail. The colour of this species is silvery, with a blueish cast on the upper parts, and several transverse, alternate, brownish shades continued along the body, accompanied by large, distant, round spots, of a similar colour: the fins and processes deep crimson: the pectoral fins pretty large in proportion.

It appears from a print published in the year 1798, that a specimen of this fish was thrown on the coast of Cornwall in the month of February in the same year. Its length was eight feet six inches, its breadth in the widest part ten inches and a half, and its thickness only two inches and three quarters; the tail in this specimen was wanting: the colours the same as in the specimen figured by Dr. Bloch.

GYMNOSOPHISTS, a sect of philosophers who clothed themselves no farther than modesty required. There were some of these sages in Africa; but the most celebrated clan of them was in India. The African gymnosophists dwelt upon a mountain in Ethiopia, near the Nile, without the accommodation either of house or cell. They did not form themselves into societies like those of India, but each had his private retirement, where he studied and performed his devotions by himself. If any person had killed another by chance, he applied to these sages for absolution, and submitted to whatever penances they enjoined. They observed an extraordinary frugality, and lived only upon the fruits of the earth. Lucan ascribes to these gymnosophists several new discoveries in astronomy.

The Indian gymnosophists dwelt in the woods, where they lived upon the wild products of the earth, and never drank wine, nor married. Some of them practised physic,

and travelled from one place to another: these were particularly famous for their remedies against barrenness. Some of them, likewise, pretended to practise magic, and to foretell future events.

GYMNOSPERMIA, in botany, from *γυμνός* naked, and *σπέρμα*, seed; the first order in Linnæus's class of didynamia. It comprehends those plants of that class which have naked seeds. The seeds are constantly four in number, except in one genus, viz. *phryma*, which is monospermous.

GYMNOTUS, *gymnote*, a genus of fishes belonging to the apodes. The generic character is, head with lateral opercula; tentacula two on the upper lip; eyes covered by the common skin; gill-membrane five-rayed; body compressed, without dorsal fin (in most species), but carinated by a fin beneath. The most remarkable species, are:

1. The *gymnotus electricus*, a native of the warmer regions of Africa and America, where it inhabits the larger rivers, and is particularly found in those of Surinam. In Africa it is said chiefly to occur in the branches of the river Senegal. It is a fish of a disagreeable appearance; bearing a general resemblance to a large eel, though somewhat thicker in proportion, and of a much darker colour, being commonly of an uniform blackish-brown. It is usually seen of the length of three or four feet, but is said to arrive at a far larger size, specimens occasionally occurring of 6, 7, or even 10 feet in length. It was first made known to the philosophers of Europe about the year 1671, when its wonderful properties were announced to the French academy by Mons. Richer, one of the gentlemen sent out by the academy to conduct some mathematical observations in Cayenne. This account however seems to have been received with a degree of cautious scepticism by the major part of European naturalists; and it was not till towards the middle of the last century that a full and general conviction appears to have taken place; the observations of Mons. Condamine, Mr. Ingram, Mr. Gravesend, and others, then conspiring to prove that the power of this animal consists in a species of real electricity, being conducted by similar conducting substances, and intercepted by others of an opposite nature. Thus, on touching the fish with the fingers, the same sensation is perceived as on touching a charged phial; being sometimes felt as far as the elbows; and if touched by both hands, an electric shock is conveyed through the breast in the usual manner. Fermin, in particular, who, during his residence in Surinam, had frequent opportunities of examining the animal, demonstrated by experiment that 14 slaves, holding each other by the hands, received the shock at the same instant; the first touching the fish with a stick, and the last dipping his hand into the water in which it was kept. The experiments of Dr. Bancroft were equally satisfactory (see **ELECTRICITY**). It is by this extraordinary faculty that the *gymnotus* supports its existence: the smaller fishes and other animals which happen to approach it, being instantly stupified, and thus falling an easy prey to the electrical tyrant. So powerful is the shock which this fish, in its native waters, is capable of exerting, that it is said to deprive almost entirely of sense and motion those who are exposed

to its approach, and is therefore much dreaded by those who bathe in the rivers which it inhabits. See *Pl. Nat. Hist.* fig. 218.

It has been affirmed that the *gymnotus electricus*, even for some time after its death, cannot be touched without feeling its electric shock. This is by no means incredible, when we consider the effect of the galvanic pile, so well known to modern philosophers.

2. *Gymnotus carapo*. The head of the *carapo* is of a compressed form, and the upper jaw projects beyond the lower: the tongue is short, thick, broad, and furnished like the jaws with a great many small sharp-pointed teeth: the eyes are very small, and the front of the head is marked, as in the preceding species, by a number of small round pores: the body gradually decreases towards the tail, which is extremely slender, and terminates in a point. The colour of the whole animal is brown, marked by a few irregular spots or patches of a deeper cast: the scales are small, and the lateral line straight. This fish is a native of the American seas, and is said to be most frequent about the coast of Surinam. It is supposed to live chiefly on small fishes, sea insects, &c. Whether it possesses any electric power, like the former species, may be doubted; yet the structure of the lower part of the body seems to imply somewhat of a similar contrivance of nature. The usual length of the *carapo* is from 1 to 2 feet; but it is sometimes found of the length of three feet, and of the weight of more than ten pounds. It is considered as an esculent fish by the South Americans.

3. *Gymnotus rostratus*, or rostrated *gymnote*. In its general aspect this species is much allied to the *carapo*, but is readily distinguished by the peculiar form of the head, which terminates in a narrow, slightly compressed, tubular snout, the jaws appearing in a manner connate: the colour of the body is pale reddish-brown, variegated with differently sized spots of a darker colour, and which are much smaller, as well as more numerous, on the fin than on the other parts: the pectoral fins are round, and rather small for the size of the animal: the eyes are very small: the scales, if any, are so small as to be not distinctly visible on a general view. This species is a native of Surinam, and seems to have been first described and figured by Seba.

4. *Gymnotus acus*, or needle *gymnote*. This species is described by Brunnich, in his history of the fish of Marseilles. It is whitish, with reddish and brown spots, which cause a kind of clouded variegation on the back, while a blueish tinge prevails towards the under parts: on the back is a kind of projection, which may be rather considered as a rudiment of a fin than a perfect one: the whole animal is of a long, compressed, and attenuated form, and the mouth is destitute of tentacula. This is the only European species of *gymnote* yet discovered, and is a native of the Mediterranean sea. Beside these there are 11 other species.

GYNANDRIA, from *γυνή*, a woman, and *ανρ*, a man, the name of the 20th class in Linnæus's sexual system, consisting of plants with hermaphrodite flowers, in which the stamina are placed upon the style, or, to speak more properly, upon a pillar-shaped recepta-

cle resembling a style, which rises in the middle of the flower, and bears both the stamina and pointal; that is, both the supposed organs of generation (see **BOTANY**). The flowers of this class, says Linnæus, have a monstrous appearance; arising, as he imagines, from the singular and unusual situation of the parts of fructification.

GYNOPOGON, a genus of the pentandria monogynia class and order. The calyx is half five-cleft; corolla five-parted; stigma globular, two-lobed; berry pedicelled, subglobular; seed cartilaginous. There are three species, herbs of the South Seas, of no note.

GYPSUM. See **LIME**, *sulphat of*.

What formerly was called gypsum, or selenite, is now known to be a sulphat of lime. It is also distinguished by the name of plaster stone, &c.

GYRINUS, or glimmerchaffer, a genus of insects of the coleoptera order. The generic character is, antennæ clavated, stiff, shorter than the head; eyes (apparently) four, two above and two below.

The genus *gyrinus* is furnished with extremely short, stiff antennæ, appearing to consist of an undivided piece or joint; but, if accurately inspected by means of a magnifier, they will be found to be composed of very numerous close-set joints: the eyes are so placed as to appear double on each side the head, viz. one above, and the other below the base of the antennæ.

The most remarkable European species is the *gyrinus natator*, a small insect, about a quarter of an inch in length, of an oval shape, with somewhat sharpened extremities, and of a black or grey-black colour, with so lucid a surface as to shine like a piece of looking-glass in the full sunshine. It is an inhabitant of the waters, and is chiefly found in rivulets, being generally seen in great multitudes, and in very brisk motion. It is difficult to catch, diving with astonishing celerity when disturbed; the hinder legs being very broad, finely webbed with minute hairs, and most curiously formed for exercising the office of fins or oars. The larva is of a highly singular aspect, having a very lengthened body, furnished, exclusive of six legs on the fore-parts, with a great many lateral appendages or processes down the body; those towards the extremity considerably exceeding the rest. In its motions it is extremely agile, swimming in a kind of serpentine manner, and preying on the smaller and weaker water-insects, minute worms, &c.; the head is armed with a pair of forceps, pierced on each side the tip with a small foramen, through which it sucks the juices of the animals on which it preys; the colour of this larva is a very pale or whitish brown, with a high degree of transparency, which renders it a very curious object for the microscope: its length, when full-grown, is about three quarters of an inch. When the time of its changes arrives, it forms for itself a small oval cell or case on a leaf of sedge, or other convenient water-plant, and, after casting its skin, becomes a chrysalis: this change usually takes place in the month of August, and the complete insect emerges in that of September.

When these animals are congregated together in great multitudes on the surface of the water, which frequently happens in hot

weather, they have been observed to diffuse a strong or disagreeable smell to a considerable distance. Like other water-beetles they fly only by night. They deposit their eggs, which are very small, white, and of a somewhat cylindric form, on the stems of water-plants; they hatch in the space of about eight

days, and immediately begin to swim about with much briskness in quest of prey. There are only 2 species.

GYRFALCON. See FALCO.

GYPSIES. See EGYPTIANS.

GYPSOPHILA, a genus of the digynia

order, in the decandria class of plants, and in the natural method ranking under the 22d order, caryophyllei. The calyx is monophyllous, campanulate, and angulated; the petals are five in number, ovate, and sessile; the capsule globose and unilocular. There are 12 species, herbs of Europe.

H.

H, the eighth letter in our alphabet; used as a numeral, denotes 200; and with a dash over it, $\bar{H}$, 200,000.

As an abbreviation, H was used by the ancients to denote *homo*, *hæres*, *hora*, &c. Thus H. B. stood for *hæres bonorum*; and H. S. corruptly for L. L. S. a sesterce; and H. A. for Hadrianus.

HABDALA, a ceremony of the Jews, observed on the sabbath in the evening; intended to signify that the sabbath is over, and is from that moment divided from the day of labour which follows. For this reason the ceremony is called *habdala*, which signifies distinction.

HABEAS CORPUS. This writ formed part of the antient common law, but was much more restrained in its operation and effects; for the judges arrogated to themselves the power of granting or denying it; and the gaolers did not pay a proper attention to it, often putting the sufferer to the expence of an alias and pluries *habeas corpus* before they obeyed. These inconveniences produced the famous statute 31 Car. II. c. 2.

This great bulwark of English liberty, which may fairly be put upon a level with the celebrated Magna Charta, was occasioned by the unjust oppression of an insignificant individual in the reign of Charles the Second. The statute enacts,

1st. That the lord chancellor, or any of the judges in vacation, on complaint or written request of any person committed for any crime (except felony, or treason, or as accessory, or suspected of being accessory before the fact, to any petty treason, or felony, or charged in execution by legal process), upon seeing a copy of the warrant, or affidavit that copy is denied, shall award a *habeas corpus* for such prisoner, returnable immediately before himself, or any other of the judges (unless the party has suffered two terms to elapse before applying to the court for his liberation), and shall discharge the party, if bailable, on his giving proper security to appear.

2dly. That the writ shall be indorsed, as granted in pursuance of this act, and signed by the person awarding it.

3dly. That the writ shall be returned, and the prisoner brought up in a limited time, according to the distance, never exceeding 20 days.

4thly. That officers and keepers not making due returns, or not delivering to the party or his agent, within six hours after demand, a

copy of the warrant of commitment, or shifting the custody of a prisoner without proper authority (as mentioned in the act), shall forfeit 100*l.* for the first offence, and 200*l.* for the second, to the sufferer, and be disabled from holding such office.

5thly. That any one detaining a person once delivered by *habeas corpus* for the same offence, shall forfeit 500*l.*

6thly. That every person committed for treason or felony shall, if he desires it, the first week of the next term, or the first day of the next session of oyer and terminer, be indicted in that term or session, or else admitted to bail, unless the witnesses for the crown cannot be produced at that time; and if acquitted, or not indicted, and tried in the second term or session, shall be discharged; but no person after the commencement of assizes for the county where he is detained, shall be removed by *habeas corpus* till they are ended.

7thly. That a prisoner can obtain his *habeas corpus* out of the chancery and exchequer, as well as out of the king's bench and common pleas; and if the chancellor and judges shall refuse the same on sight of the warrant or oath that it is denied, shall forfeit severally 500*l.* to the party grieved.

8thly. That this writ of *habeas corpus* shall run into the counties palatine, and all other privileged places, and the islands of Guernsey and Jersey.

9thly. That no inhabitants of England (unless at their desire, or having committed some capital offence in the place to which they are sent), shall be sent prisoners to Ireland, Scotland, Guernsey, and Jersey, or any places beyond the seas, within or without his majesty's dominions, on pain that the person committing, and his advisers and abettors, shall forfeit to the injured party a sum not less than 500*l.* to be recovered with treble costs, shall be disabled from holding any office, shall incur the penalties of *præmunire*, and be incapable of the king's pardon.

The writs in use under this act are various. Many kinds are used for removing prisoners from one court to another. Such are the *habeas corpus ad respondendum*, when a man has cause of action against one who is confined by process of an inferior court, in order to remove the prisoner, and charge him with this new action in the court above. *Ad satisfaciendum* is when judgment has, in an action, been given against a prisoner; and the plaintiff brings him up to a superior court to charge him with process of execution. Also the writs *ad prosequen-*

dum, testificandum, deliberandum, which issue when it is necessary to remove a prisoner, in order to prosecute, or bear testimony, or to be tried in the proper jurisdiction wherein the fact was committed. And, lastly, the common writ *ad faciendum et recipiendum*, which issues out of any of the courts above, when a person is sued in some inferior jurisdiction, and desires to remove the action into the superior court, commanding the inferior judges to produce the body of the defendant, with the day and cause of his detainer, to do and receive what the king's court shall determine. This writ is grantable of common right, without moving the court, and supercedes all inferior proceedings. But to prevent the surreptitious discharge of prisoners, the statute 1 and 2 P. & M. c. 13, enacts, that no *habeas corpus* shall issue to remove any prisoner out of gaol, unless signed by some judge of the court out of which it is awarded. And by a statute of the present reign it is enacted, that no cause under the value of 10*l.* shall be removed into a superior court, unless the defendant, on removing the same, gives security for payment of debt and costs.

But the writ which forms so great a part of the liberty of the subject in all manner of illegal confinement, is the *habeas corpus ad subjiciendum*, commanding the person detaining a prisoner to produce him, with the day and cause of his detention, to submit to whatever the judge or court awarding such writ shall determine. This is a high prerogative writ, and therefore, by the common law, issuing out of the court of king's bench, not only in term time, but vacation, by a fiat from any of the judges, and running into all the king's dominions. And a man has now the benefit of the common law writ, either in the king's bench or common pleas, as he chooses; and in both those courts it is necessary to apply for it by motion, as it does not issue of course, without shewing some reason for the granting it. But if good grounds be shewn that the party is imprisoned without just cause, it becomes a writ of common right, and must not be denied, even though a man is detained by the highest authority.

This celebrated act has been subject to temporary suspensions, by authority of parliament, in times of riot or rebellion; and the late minister subjected himself to considerable unpopularity by that measure during the last war.

HABENDUM, in a deed, is to determine what estate or interest is granted by the deed,

the certainty thereof, for what time, and to what use. It sometimes qualifies the estate, so that the general implication thereof, which, by construction of law, passes in the premises, may by the habendum be controlled: in which case the habendum may lessen or enlarge the estate, but not totally contradict or be repugnant to it. As if a grant is to one and the heirs of his body, to leave to him and his heirs for ever, here he has an estate tail by the grant, and by the habendum he has a fee simple expectant thereon. But if it had been in the premises to him and his heirs, to have for life, the habendum would be utterly void; for an estate of inheritance is vested in him before the habendum comes, and shall not afterwards be taken away, or divested by it. 2 Black. 298.

The habendum cannot pass any thing that is not expressly mentioned, or contained by implication in the premises of the deed; because the premises being part of the deed by which the thing is granted, and consequently that makes the gift; it follows that the habendum, which only limits the certainty and extent of the estate in the thing given, cannot increase or multiply the gift, because it would be absurd to say that the grantee shall hold a thing which was never given him. 2 Roll. Abr. 65. See DEED.

HABERDASHER, in commerce, a seller of hats, or of small wares.

The master and wardens of the company of haberdashers in London, calling to their assistance one of the company of cappers, and another of the hat-makers, and mayors, &c. of towns, may search the wares of all hatters that work hats with foreign wool, and have not been apprentices to the trade, or who dye them with any thing but copperas and galls, or woad and madder; in which case they are liable to penalties, by stat. 8 Eliz. c. 7, and 5 Geo. II. c. 22.

HABERE FACIAS SEISINAM, a writ of execution directed to the sheriff, commanding him to give to the plaintiff possession of a freehold: if it is a chattel interest, and not a freehold, then the writ is entitled *habere facias possessionem*. 3 Black. 412.

In the execution of these writs, the sheriff, if needful, may take with him the power of the county, and may justify breaking open doors, if the possession is not quietly delivered; but if it is peacefully delivered up, the yielding of a twig, a turf, or the ring of a door, in the name of seisin, is sufficient. Id.

HABERE FACIAS VISUM, a writ that lies in divers cases in real actions, as in dower, formedon, &c. where view is required to be taken of the lands or tenements in question.

HABERGEON, a small coat of mail, or only sleeves and gorget of mail, formed of little iron rings or meshes linked into each other.

HADDOCK. See GADUS.

HÆMANTHUS, the *blood flower*, a genus of the monogynia order, in the hexandria class of plants, and in the natural method ranking under the ninth order, spathaceæ. The involucre is hexaphyllous and multiflorous; the corolla sexpartite, superior; the berry trilocular. There are eight species, of which the principal are:

1. The *coccineus*, with plain tongue-shaped leaves, rises about a foot high, with a stalk supporting a cluster of bright-red tubulous

flowers. It has a large bulbous root, from which in the autumn come out two broad flat leaves of a fleshy consistence, shaped like a tongue, which turn backward on each side, and spread on the ground, so that they have a strange appearance all the winter. In the spring these decay; so that from May to the beginning of August they are destitute of leaves. The flowers are produced in the autumn just before the leaves come out.

2. The *carinatus*, with keel-shaped leaves, has a taller stalk and paler flowers than the former; its leaves are not flat, but hollowed like the keel of a boat.

3. The *puniceus*, with large spear-shaped waved leaves, grows about a foot high, and has flowers of a yellowish-red colour. These are succeeded by berries, which are of a beautiful red colour when ripe. All these plants are natives of the Cape of Good Hope.

HÆMATITES, or *blood stone*, a hard mineral substance, red, black, or purple, but the powder of which is always red. It is found in masses sometimes spherical, semi-spherical, pyramidal, or cellular, that is, like a honeycomb. It contains a large quantity of iron. Forty pounds of that metal have been extracted from a quintal of stone; but the iron is of such a bad quality, that this ore is not commonly smelted. The great hardness of hæmatites renders it fit for burnishing and polishing metals. The specific gravity from 47 to 50. See Pl. Nat. Hist. fig. 220.

HÆMATOPUS, the *sea-pye*, in ornithology, a genus belonging to the order of grallæ. The beak is compressed, with an equal wedge-shaped point; the nostrils are linear; and the feet have three toes without nails. There is but one species, viz. the *ostralegus*, or oyster-catcher, a native of Europe and America. See Pl. N. H. fig. 219. It feeds upon shell-fish near the sea-shore, particularly oysters and limpets. On observing an oyster which gapes wide enough for the insertion of its bill, it thrusts it in, and takes out the inhabitant: it will also force the limpets from their adhesion to the rocks with sufficient ease. Occasionally it feeds on marine insects and worms. With us these birds are often seen in considerable flocks in winter: in the summer they are met with only in pairs, though chiefly in the neighbourhood of the sea or salt rivers.

HÆMATOXYLUM, *logwood*, or *Campeachy wood*, a genus of the monogynia order, in the decandria class of plants, and in the natural method ranking under the 33d order, lomentaceæ. The calyx is quinquepartite; the petals five; the capsule lanceolated, unilocular, and bivalved; the valves navicular, or keeled like a boat. Of this genus there is only one species, viz. the *campechianum*, which grows naturally in the bay of Campeachy at Honduras, and other parts of the Spanish West Indies, where it rises from 16 to 24 feet high. The stems are generally crooked, and very deformed, and seldom thicker than a man's thigh. The branches, which come out on each side, are crooked, irregular, and armed with strong thorns, and winged leaves, composed of three pair of obscure lobes indented at the top. The flowers come in a racemus from the wings of the leaves, standing erect, and are of a pale-yellowish colour, with a purple empalement. They are succeeded by flat oblong pods, each containing two or three kidney-seeds.

Logwood is used in great quantities for dyeing purple, but especially black colours. All the colours, however, which can be prepared from it, are of a fading nature, and cannot by any art be made equally durable with those prepared from some other materials. Of all the colours prepared from logwood, the black is the most durable. Doctor Lewis recommends it as an ingredient in making ink. "In dyeing cloth (says he), vitriol and galls, in whatever proportions they are used, produce only browns of different shades: I have often been surprised that with these capital materials of the black dye I never could obtain any true blackness in white cloth, and attributed the failure to some unheeded mismanagement in the process, till I found it to be a known fact among the dyers. Logwood is the material which adds blackness to the vitriol and gall brown; and this black dye, tho' not of the most durable kind, is the most common. On blue cloth a good black may be dyed by vitriol and galls alone; but even here an addition of logwood contributes not a little to improve the colour." Mr. Delaval, however, in his Essay on Colours, informs us, that with an infusion of galls and iron-filings, he not only made an exceeding black and durable ink, but also dyed linen cloth of a very deep black.

HÆMOPTOSIS, in medicine, a spitting of blood. See MEDICINE.

HÆMORRHAGE, in medicine, a flux of blood from any part of the body. See MEDICINE.

HÆMORRHOIDS, or **PILES**. See MEDICINE.

HÆRUCA, in entomology, a genus of the order of vermes intestina. The body is round, the fore part two-necked, and surrounded with a single row of prickles. The *H. muris* is grey-white and wrinkled: it inhabits the intestines of the mouse, and is distinguished from the *echin* or *hynchus*, in wanting the retractile proboscis.

HAIL, in natural history, a meteor generally defined frozen rain, but differing from it in that the hailstones are not formed of single pieces of ice, but of many little spherules agglutinated together. Neither are these spherules all of the same consistence; some of them being hard and solid like perfect ice; others soft, and mostly like snow hardened by a severe frost. Sometimes the hailstone has a kind of core of this soft matter; but more frequently the core is solid and hard, while the outside is formed of a softer matter. Hailstones assume various figures, being sometimes round, at other times pyramidal, crenated, angular, thin, and flat, and sometimes stellated, with six radii like the small crystals of snow. See METEOROLOGY.

Natural historians furnish us with various accounts of surprising showers of hail, in which the hailstones were of extraordinary magnitude. Mezeray, speaking of the war of Louis XII. in Italy, in the year 1510, relates, that there was for some time a horrible darkness, thicker than that of night; after which the clouds broke into thunder and lightning, and there fell a shower of hailstones, or rather (as he calls them) pebblestones, which destroyed all the fish, birds, and beasts, of the country. It was attended with a strong smell of sulphur; and the stones

were of a blueish colour, some of them weighing a hundred pounds. Hist. de France, tom. ii. p. 339.

At Lisle, in Flanders, in 1686, fell hailstones of a very large size; some of which contained in the middle a dark-brown matter, which, thrown on the fire, gave a very great report. Phil. Trans. No. 203.

Dr. Halley and others also relate, that in Cheshire, Lancashire, &c. April 29, 1697, a thick black cloud coming from Carnarvonshire, disposed the vapours to congeal in such a manner, that for about the breadth of two miles, which was the limit of the cloud, in its progress, for the space of 60 miles, it did inconceivable damage; not only killing all sorts of fowls and other small animals, but splitting trees, knocking down horses and men, and even ploughing up the earth; so that the hailstones buried themselves under ground an inch or an inch and a half deep. The hailstones, many of which weighed five ounces, and some half a pound, and being five or six inches about, were of various figures; some round, others half-round; some smooth, others embossed and crenated: the icy substance of them was very transparent and hard, but there was a snowy kernel in the middle of them.

In Hertfordshire, May 4, the same year, after a severe storm of thunder and lightning, a shower of hail succeeded, which far exceeded the former: some persons were killed by it, and their bodies beaten all black and blue; vast oaks were split, and fields of rye cut down as with a scythe. The stones measured from 10 to 13 or 14 inches about. Their figures were various, some oval, others picked, and some flat. Philosoph. Trans. No. 229.

Methods have lately been proposed, in England and France, to draw off the lightning, and dissipate hail-storms. Monthly Magazine, July 1806.

HAIR. See **PHYSIOLOGY**.

Hair and feathers cover different parts of animals, and are obviously intended by nature to protect them from the cold. For this their softness and pliability, and the slowness with which they conduct heat, render them peculiarly proper.

1. Hair is usually distinguished into various kinds, according to its size and appearance. The strongest and stiffest of all is called bristle: of this kind is the hair on the back of hogs. When remarkably fine, soft, and pliable, it is called wool; and the finest of all is known by the name of down. But all these varieties resemble one another very closely in their composition.

Hair appears to be a kind of tube covered with a cuticle. Its surface is not smooth, but either covered with scales, or consisting of imbricated cones. Hence the roughness of its feel, and the disposition which it has to entangle itself, which has given origin to the processes of felting and fulling. It is constantly increasing in length, being protruded from the roots, and seems at first to be soft or nearly gelatinous. From the experiments which have been made on hair by Achard and Hatchett, it follows that it contains gelatine, to which it owes its suppleness and toughness. This substance may be separated by boiling the hair in water. When thus treated it becomes much more brittle than before. Indeed if the process is continued long enough,

the hair crumbles to pieces between the fingers. The portion insoluble in water possesses the properties of coagulated albumen.

Mr. Hatchett has concluded, from his experiments, that the hair which loses its curl in moist weather, and which is the softest and most flexible, is that which yields its gelatine most easily; whereas strong and elastic hair yields it with the greatest difficulty, and in the smallest proportion. This conclusion has been confirmed by a very considerable hair-merchant in London, who assured him that the first kind of hair was much more injured by boiling than the second.

The rapidity with which hair burns, and the fusion which it undergoes in that case, shew us, however, that hair does not altogether correspond with coagulated albumen in its nature, but approaches towards the oils. When distilled, 1152 parts of hair yielded Berthollet the following products:

90 carbonat of ammonia
179 water smelling of burnt hair
288 oil
271 gases
324 coal

1152.

The oil was of a brown colour, solid unless exposed to a heat equal to 73°, very soluble in alcohol, burnt with great brilliancy, and with scintillations like hair. The charcoal was difficult to incinerate, and was attracted by the magnet; of course it contained iron. From the experiments of Fourcroy and Vauquelin, we learn that horsehair, when burnt, leaves a residuum of 0.12, which is mostly phosphat of lime.

The alkalies dissolve hair at a boiling-heat, and form with it an animal soap; but lime appears to have but little action on it. When muriatic acid is poured into the solution of hair in potass, a quantity of sulphurated hydrogen gas is disengaged, and a black substance, doubtless charcoal, precipitates. Hence it follows that it contains sulphur. Accordingly, if a bit of silver is put into the solution, it instantly assumes a black colour.

Sulphuric acid dissolves hair by the assistance of heat, some charcoal is deposited, and carbonic acid gas separates. Nitric acid tinges it yellow, and dissolves it when assisted by heat; while a fat matter separates, and oxalic acid is formed. Berthollet obtained from wool more than half its weight of oxalic acid. Muriatic acid dissolves it readily; but the solution does not become black, and has much the appearance of a solution of glue in the same acid. Oxymuriatic acid whitens hair, and destroys its strength. When the hair is plunged into the acid in the state of gas, it is very soon converted into a pulp.

2. Feathers seem to possess very nearly the same properties with hair. Mr. Hatchett has ascertained that the quill is composed chiefly of coagulated albumen. Though feathers were boiled for a long time in water, Mr. Hatchett could observe no traces of gelatine.

HAIR'S BREADTH, a measure of length, being the 48th part of an inch.

HALCYON. See **ALCEDO**.

HALE. See **HAUL**.

HALESIA, a genus of the monogynia order, in the dodecandria class of plants; and in the natural method ranking under the 18th

order, bicornes. The calyx is quadridentated, superior; the corolla quadrid; the nut quadrangular and dispermous. There are two species, herbaceous plants of N. America.

HALF-MOON, in fortification, an out-work composed of two faces, forming a salient angle, whose gorge is in form of a crescent, or half-moon; whence the name. See **FORTIFICATION**.

HALF-SEAL, that used in the court of chancery for sealing commissions to delegates, upon any appeal, in ecclesiastical or marine causes.

HALIOTIS, the ear-shell, a genus of insects belonging to the order of vermes testacea. This is an animal of the snail kind, with an open shell resembling an ear. There are nineteen species, distinguished by the figure of their shells.

HALLERIA, a genus of the angiospermia order, in the didynamia class of plants; and in the natural method ranking under the 40th order, personata. The calyx is trifid; the corolla quadrid; the filaments longer than the corolla; the berry inferior and bilocular (the fruit not yet fully described). There is one species, a shrub of the Cape.

HALO, in physiology, a meteor in the form of a luminous ring or circle, of various colours, appearing round the bodies of the sun, moon, or stars. See **OPTICS**.

HAMELLIA, a genus of the monogynia order, in the pentandria class of plants; and in the natural method ranking with those of which the order is doubtful. The corolla is quinquefid; the berry quinquelocular, inferior, polyspermous. There are four species, trees of the West Indies.

HAMMER, a well-known tool used by mechanics, consisting of an iron head, fixed crosswise upon a handle of wood.

There are several sorts of hammers used by blacksmiths; as, 1. The hand-hammer, which is of such weight that it may be wielded or governed with one hand at the anvil. 2. The up-hand sledge, used with both hands, and seldom lifted above the head. 3. The about-sledge, which is the largest hammer of all, and held by both hands at the farthest end of the handle, and being swung at arm's-length over the head, is made to fall upon the work with as heavy a blow as possible. There is also another hammer used by smiths, called a rivetting-hammer, which is the smallest of all, and is seldom used at the forge, unless upon small work.

HAMSOKEN, is used in Scotland for the crime of him that violently, and contrary to the king's peace, assaults a man in his own house, which is punishable equally with ravishing a woman.

HANAPER office, in the court of chancery, is that out of which issue all original writs that pass under the great seal, and all commissions of charitable uses, sewers, bankrupts, ideocy, lunacy, and such-like. These writs, relating to the business of the subject, and the returns to them, were originally kept in a hamper, in hanaperio; the other writs, relating to matters wherein the crown is immediately or mediately concerned, were preserved in a little sack or bag, in parva бага; and thence has arisen the distinction of the hanaper office and petty-bag office: both of which belong to the common law court in chancery. 3 Black. 48.

HANCES, in a ship, are falls or descents of the five rails, which are placed from the stern down to the gangways.

HAND. See **ANATOMY**.

HAND-BARROW, a wheelbarrow which is of great use in fortification, for carrying earth from one place to another, and in a siege, for carrying bombs or cannon-balls along the trenches.

HAND-BREADTH, a measure of three inches.

HAND-CUFFS, an instrument formed of two circular pieces of iron, each fixed on a hinge at the ends of a very short iron bar, which being locked over the wrists of a malefactor, prevents his using his hands.

HAND-GRENADES. See **GRENADES**.

HARBINGER, an officer of the king's household, having four yeomen under him, who ride a day's journey before the court, when it travels, to provide lodgings.

HARDENING, the giving a greater degree of hardness to bodies than they had before. See the article **HARDNESS**.

There are several ways of hardening iron and steel, as by hammering them, quenching them, when hot, in cold water, case-hardening, &c. See **IRON**.

HARDNESS, in bodies, a property directly opposite to fluidity; by which they resist the impression of any other substance, sometimes in an extreme degree. As fluidity has been found to consist in the motion of the particles of a body upon one another in consequence of a certain action of the universal fluid or elementary fire among them; we must conclude that hardness consists in the absence of this action, or a deficiency of what is called latent heat. This is confirmed by observing that there is an intermediate state betwixt hardness and fluidity, in which bodies will yield to a certain force, though they still make a considerable resistance. This is principally observed in the metals, and is the foundation of their ductility. It appears, indeed, that this last property, as well as fluidity, is entirely dependant on a certain quantity of caloric absorbed, or otherwise acting within the substance itself; for all the metals are rendered hard by hammering, and soft by being put again into the fire and kept there for some time. The former operation renders them hot as well as hard; probably, as Dr. Black observes, because the particles of metal are thus forced nearer one another, and those of fire squeezed out from among them. By keeping them for some time in the fire, that element insinuates itself again among the particles, and arranges them in the same manner as before, so that the ductility returns. By a second hammering this property is again destroyed, returning on a repetition of the heating, or annealing as it is called; and so on, as often as we please.

Hardness appears to diminish the cohesion of bodies in some degree, though their fragility does not by any means keep pace with their hardness. Thus, glass is very hard and very brittle; but flint, though still harder than glass, is much less brittle. Among the metals, however, these two properties seem to be more connected, though even here the connection is by no means complete. Steel, the hardest of all the metals, is indeed the most brittle; but lead, the softest, is not the most ductile. Neither is hardness connected

VOL. I.

with the specific gravity of bodies; for a diamond, the hardest substance in nature, is little more than half the weight of the lightest metal. As little is it connected with the coldness, electrical properties, or any other quality with which we are acquainted: so that though the principle above laid down may be accepted as a general foundation for our inquiries, a great number of particulars remain yet to be discovered before we can offer any satisfactory explanation.

All bodies become harder by cold; but this is not the only means of their doing so, for some become hard by heat as well as cold.

Mr. Quist and others have constructed tables of the hardness of different substances. The method pursued in constructing these tables was by observing the order in which they were able to cut or make any impression upon one another. The following table, extracted from M. Magellan's edition of Cronstedt's Mineralogy, was taken from Dr. Quist, Bergman, and Mr. Kirvan. The first column shows the hardness, and the second the specific gravity.

| | H. | S.G. |
|-----------------------|----|------|
| Diamond from Ormus | 20 | 3,7 |
| Pink diamond | 19 | 3,4 |
| Blueish diamond | 19 | 3,3 |
| Yellowish diamond | 19 | 3,3 |
| Cubic diamond | 18 | 3,2 |
| Ruby | 17 | 4,2 |
| Pale ruby from Brazil | 16 | 3,5 |
| Ruby spinell | 13 | 3,4 |
| Deep-blue sapphire | 16 | 3,8 |
| Ditto paler | 17 | 3,8 |
| Topaz | 15 | 4,2 |
| Whitish ditto | 14 | 3,5 |
| Bohemian ditto | 11 | 2,8 |
| Emerald | 12 | 2,8 |
| Garnet | 12 | 4,4 |
| Agate | 12 | 2,6 |
| Onyx | 12 | 2,6 |
| Sardonyx | 12 | 2,6 |
| Occid. amethyst | 11 | 2,7 |
| Crystal | 11 | 2,6 |
| Carnelian | 11 | 2,7 |
| Green jasper | 11 | 2,7 |
| Reddish-yellow ditto | 9 | 2,6 |
| Schoerl | 10 | 3,6 |
| Tourmaline | 10 | 3,0 |
| Quartz | 10 | 2,7 |
| Opal | 10 | 2,6 |
| Chrysolite | 10 | 3,7 |
| Zeolite | 8 | 2,1 |
| Fluor | 7 | 3,5 |
| Calcareous spar | 6 | 2,7 |
| Gypsum | 5 | 2,3 |
| Chalk | 3 | 2,7 |

HARE. See **LEPUS**.

HARIOT. See **HERIOT**.

HARMATTAN. The harmattan is a very singular wind, which blows periodically from the interior parts of Africa towards the Atlantic Ocean. The season in which it prevails is during the months of December, January, and February; it comes on indiscriminately at any hour of the day, at any time of the tide, or at any period of the moon, and continues sometimes only a day or two, sometimes five or six days, and it has been known to last fifteen and sixteen days. There are generally three or four returns of it every season. It blows with a moderate force, but not quite so strong as the sea-breeze.

5 X

A fog or haze is one of the peculiarities which always accompany the harmattan. The English, French, and Portuguese forts at Whydah, are not quite a quarter of a mile asunder, yet are frequently quite invisible to each other; the sun, concealed the greatest part of the day, appears only about a few hours at noon, and then of a mild red, exciting no painful sensation on the eye. The particles which constitute this fog are deposited on the leaves of trees, on the skins of the negroes, &c. and make them appear whitish.

Extreme dryness makes another extraordinary property of this wind; no dew falls during its continuance; vegetables are withered, and the grass becomes dry like hay. The natives take this opportunity to clear the land, by setting fire to the trees and plants while in that dry and exhausted state. The dryness is so extreme, that the covers of books, even closely shut up in a trunk, are bent as if exposed to the fire. Household furniture is much damaged; the pannels of wainscots split, and fineered work flies to pieces. The joints of a well-laid floor of seasoned wood open sufficiently to admit the breadth of a finger between them; but become as close as before on the ceasing of the harmattan. The human body does not escape the parching effects of this wind; the eyes, nostrils, lips, and palate, are rendered dry and uneasy; the lips and nose become sore, and though the air is cool, there is a troublesome sensation of pricking heat on the skin. If the harmattan continues four or five days, the scarf-skin peels off, first from the hands and face, and afterwards from the rest of the body.

Though this wind is so fatal to vegetable life, and occasions these troublesome effects to the human species, it is nevertheless highly conducive to health; it stops the progress of epixemics, and relieves the patients labouring under fluxes and intermittent fevers. Infection is not easy at that time to be communicated, even by inoculation. It is also remarkable for the cure of ulcers and cutaneous diseases. Econ. of Nat. b. 5.

HARMONICA. This word, when originally appropriated by Dr. Franklin to that peculiar form or mode of musical glasses, which he himself, after a number of happy experiments, had constituted, was written *Armonica*. It is derived from the Greek word *ἀρμονία*. The radical word is *ἀγιν*, to suit or fit one thing to another. Relations or aptitudes of sound, in particular, were understood by it; and in this view, Dr. Franklin could not have selected a name more expressive of its nature and genius for the instrument which we are now to describe; as, perhaps, no musical tone can possibly be finer, nor consequently susceptible of juster records, than those which it produces.

"Mr. Puckridge, a gentleman from Ireland, was," says Dr. Franklin, "the first who thought of playing tunes formed of these tones. He collected a number of glasses of different sizes; fixed them near each other on a table; and tuned them, by putting into them water, more or less as each note required. The tones were brought out by pressing his fingers round their brims. He was unfortunately burnt here, with his instrument, in a fire which consumed the house that he lived in. Mr. E. Deleval, a most ingenious member of our royal society, made one in imitation of it,

with a better choice and form of glasses, which was the first I saw or heard. Being charmed with the sweetness of its tones, and the music he produced from it, I wished to see the glasses disposed in a more convenient form, and brought together in a narrower compass, so as to admit of a greater number of tones, and all within reach of hand to a person sitting before the instrument; which I accomplished, after various intermediate trials, and less commodious forms, both of glasses and construction, in the following manner:

"The glasses are blown as nearly as possible in the form of hemispheres, having each an open neck or socket in the middle. The thickness of the glass near the brim is about the tenth of an inch, or hardly so much, but thicker as it comes nearer the neck; which in the largest glasses is about an inch deep, and an inch and a half wide within; these dimensions lessening as the glasses themselves diminish in size, except that the neck of the smallest ought not to be shorter than half an inch. The largest glass is nine inches diameter, and the smallest three inches. Between these there are 23 different sizes, differing from each other a quarter of an inch in diameter. To make a single instrument there should be at least six glasses blown of each size; and out of this number one may probably pick 37 glasses (which are sufficient for three octaves with all the semitones) that will be each either the note one wants, or a little sharper than that note, and all fitting so well into each other as to taper pretty regularly from the largest to the smallest. It is true that there are not 37 sizes; but it often happens that two of the same size differ a note or half a note in tone, by reason of a difference in thickness, and these may be placed one in the other without sensibly hurting the regularity of the taper form.

"The glasses being chosen, and every one marked with a diamond the note you intend it for, they are to be tuned by diminishing the thickness of those that are too sharp. This is done by grinding them round from the neck towards the brim, the breadth of one or two inches as may be required; often trying the glass by a well-tuned harpsichord, comparing the note drawn from the glass by your finger with the note you want, as sounded by that string of the harpsichord. When you come near the matter, be careful to wipe the glass clean and dry before each trial, because the tone is something flatter when the glass is wet than it will be when dry; and grinding a very little between each trial, you will thereby tune to great exactness. The more care is necessary in this, because if you go below your required tone, there is no sharpening it again but by grinding somewhat off the brim, which will afterwards require polishing, and thus increase the trouble.

"The glasses being thus tuned, you are to be provided with a case for them, and a spindle on which they are to be fixed. My case is about three feet long, eleven inches every way wide within at the biggest end, and five inches at the smallest end; for it tapers all the way, to adapt it better to the conical figure of the set of glasses. This case opens in the middle of its height, and the upper part turns up by hinges fixed behind. The spindle is of hard iron, lies horizontally from end to end of the box within, exactly in the middle, and is made to turn on brass gudgeons

at each end. It is round, an inch diameter at the thickest end, and tapering to a quarter of an inch at the smallest. A square shank comes from its thickest end through the box, on which shank a wheel is fixed by a screw. This wheel serves as a fly to make the motion equable, when the spindle, with the glasses, is turned by the foot like a spinning-wheel. My wheel is of mahogany, 18 inches diameter, and pretty thick, so as to conceal near its circumference about 25 lb. of lead. An ivory pin is fixed in the face of this wheel, about four inches from the axis. Over the neck of this pin is put the loop of the string that comes up from the moveable step to give it motion. The case stands on a neat frame with four legs.

"To fix the glasses on the spindle, a cork is first to be fitted in each neck pretty tight, and projecting a little without the neck, that the neck of one may not touch the inside of another when put together, for that would make a jarring. These corks are to be perforated with holes of different diameters, so as to suit that part of the spindle on which they are to be fixed. When a glass is put on, by holding it stiffly between both hands, while another turns the spindle, it may be gradually brought to its place. But care must be taken that the hole be not too small, lest in forcing it up, the neck should split; nor too large, lest the glass, not being firmly fixed, should turn or move on the spindle, so as to touch or jar against its neighbouring glass. The glasses thus are placed one in another; the largest on the biggest end of the spindle, which is to the left hand: the neck of this glass is towards the wheel; and the next goes into it in the same position, only about an inch of its brim appearing beyond the brim of the first; thus proceeding, every glass when fixed shews about an inch of its brim (or three quarters of an inch, or half an inch, as they grow smaller) beyond the brim of the glass that contains it; and it is from these exposed parts of each glass that the tone is drawn, by laying a finger on one of them as the spindle and glasses turn round.

"My largest glass is G a little below the reach of a common voice, and my highest G, including three complete octaves. To distinguish the glasses more readily by the eye, I have painted the apparent parts of the glasses within side, every semitone white, and the other notes of the octave with the seven prismatic colours; viz, C, red; D, orange; E, yellow; F, green; G, blue; A, indigo; B, purple; and C, red again; so that the glasses of the same colour (the white excepted) are always octaves to each other.

"This instrument is played upon by sitting before the middle of the set of glasses, as before the keys of a harpsichord, turning them with the foot, and wetting them now and then with a sponge and clean water. The fingers should be first a little soaked in water, and quite free from all greasiness; a little fine chalk upon them is sometimes useful, to make them catch the glasses and bring out the tone more readily. Both hands are used, by which means different parts are played together. Observe, that the tones are best drawn out when the glasses turn from the ends of the fingers, not when they turn to them.

"The advantages of this instrument are,

that its tones are incomparably sweet beyond those of any other; that they may be swelled and softened at pleasure by stronger or weaker pressures of the finger, and continued to any length; and that the instrument being once well tuned, never again wants tuning."

"Analogous to these sounds," says a writer in the Annual Register, "are those produced by bells: in those last, besides the tones produced by their elliptical vibrations, there are a set of tones which may be brought by gently rubbing their edges, and in which the whole instrument does not appear to vibrate in all its parts as before.

"Take, for instance, a bell finely polished at the edges; or, what will perhaps be more convenient, a drinking-glass: let the edges be as free from any thing oily as possible; then, by moistening the finger in water (I have found alum-water to be best), and rubbing it circularly round the edge of the glass, you will at length bring out the tone referred to.

"This note is possessed of infinite sweetness: it has all the excellences of the tone of a bell, without its defects. It is loud, has a sufficient body, is capable of being swelled and continued at pleasure; and besides, has naturally that vibratory softening which musicians endeavour to imitate by mixing with the note to be played a quarter-tone from below.

"To vary these tones, nothing more is required than to procure several bells or glasses of different tones, tuned as nearly as possible, which may be done by thinning the edges of either: or, for immediate satisfaction, the glasses may be tuned by pouring in water; the more water is poured in, the graver the tone will be.

"Let us suppose then a double octave of those glasses, thus tuned, to be procured. Any common tune may be executed by the fingers rubbing upon each glass successively; and this I have frequently done without the least difficulty, only choosing those tunes which are slow and easy. Here then are numbers of delicate tones, with which musicians have been till very lately unacquainted; and the only defect is, that they cannot be made to follow each other with that celerity and ease which is requisite for melody. In order to remedy this, I took a large drinking-glass, and by means of a wheel and gut, as in the electrical machine, made it to turn upon its axis with a moderately quick but equable motion; then moistening the finger as before, nothing more was required than merely to touch the glass at the edge, without any other motion, in order to bring out the tone.

"Instead of one glass only turning in this manner, if the whole number of glasses were so fixed as to keep continually turning by means of a wheel, it follows, that upon every touch of the finger a note would be expressed; and thus, by touching several glasses at once, a harmony of notes might be produced, as in a harpsichord.

"As I write rather to excite than satisfy the curious, I shall not pretend to direct the various ways this number of glasses may be contrived to turn; it may be sufficient to say, that if the glasses are placed in the segment of a circle, and then a strap, as in a cutler's wheel, is supposed to go round them all, the whole number will by this means be made to turn by a wheel.

"Instead of the finger, I have applied moistened leather to the edge of the glass, in order to bring out the tone: but, for want of a proper elasticity, this did not succeed. I tried cork, and this answered every purpose of the finger; but made the tone much louder than the finger could do. Instead, therefore, of the finger, if a number of corks were so contrived as to fall with a proper degree of pressure on the edge of the glass; by means of keys like the jacks of an organ, it is evident, that in such a case a new and tolerably perfect instrument would be produced; not so loud indeed as some, but infinitely more melodious than any."

HARMONICAL ARITHMETIC, that part of arithmetic which considers musical intervals, expressed by numbers, in order to our finding their mutual relations, compositions, and resolutions.

HARMONICAL PROPORTION. See **PROPORTION**.

HARMONICAL SERIES, a series of many numbers in continual harmonical proportion. Thus if there are four or more numbers, of which every three immediate terms are harmonical, the whole will make an harmonical series: such is 30: 20: 15: 12: 10. Or, if every four terms immediately next each other are harmonical, it is also a continual harmonical series, but of another species, as 3, 4, 6, 9, 18, 36, &c.

HARMONY, in music (from the Greek), the agreement or consonance of two or more united sounds. Harmony is either natural or artificial. Natural harmony, properly so called, consists of the harmonic triad, or common chord. Artificial harmony is a mixture of concords and discords, bearing relation to the harmonic triad of the fundamental note. The word harmony being originally a proper name, it is not easy to determine the exact sense in which it was used by the Greeks; but from the treatises they have left us on the subject, we have great reason to conclude that they limited its signification to that agreeable succession of sounds which we call air, or melody. The moderns, however, do not dignify a mere succession of single sounds with the appellation of harmony: for the formation of harmony they require an union of melodies, a succession of combined sounds composed of consonant intervals, and moving according to the stated laws of modulation. But as the laws of harmony were not established into a code but by very slow degrees, its principles for a long time consisted of no other than almost arbitrary rules, founded, indeed, on the approbation of the ear, but unsanctioned by that science which accounts for effects rationally, and deduces its conclusions from minute, profound, and satisfactory investigation. At length, however, writers arose, to whose patience, talents, and learning, the present age is indebted for a complete system of harmony and modulation, and to whose labours we only have to resort, to be informed on every point requisite both to its theory and practice.

HARMONY, FIGURED. Figured harmony is that in which, for the purpose of melody, one or more of the parts of a composition move during the continuance of a chord, through certain notes which do not form any of the constituent parts of that chord. These intermediate notes not being reckoned in the harmony, considerable judgment and skill

are necessary so to dispose them that while the ear is gratified with their succession, it may not be offended at their dissonance with respect to the harmonic notes. See **SOUNDS**.

HARP, a stringed instrument, consisting of a triangular frame, and the chords of which are distended in parallel directions from the upper part to one of its sides. Its scale extends through the common compass, and the strings are tuned by semitonic intervals. It stands erect, and when used, is placed at the feet of the performer, who produces its tones by the action of the thumb and fingers of both hands on the strings. That the harp is among the most ancient of musical instruments, the frequent mention of it in scripture, and the splendid account transmitted to us of the Theban harp, both as to the beauty of its decorations and extent of scale, are sufficient evidences. The Irish and Welsh practised the harp long before the gammut of Guido was invented, and it is, indeed, their national instrument. In England also it was early introduced to general use, and the most ancient poems were sung to it on Sundays and all public festivals.

HARPING-IRON, or **HARPOON**, a large spear or javelin, made of forged iron, and five or six feet long; it is fastened to a line, and used in the whale-fishery.

HARPINGS, in a ship, properly denote her breadth at the bow. Some also give the same name to the ends of the bends that are fastened into the stern.

HARPOON-GUN, a sort of fire-arm for discharging harpoons at whales, and thereby killing them more expeditiously than when harpoons are thrown by the hand. See **Transactions of the Society for the Encouragement of Arts, &c.** 1786, 1789, &c.

HARPSICORD, a stringed instrument, consisting of a case formed of mahogany or walnut-tree wood, and containing the belly or sounding-board, over which the wires are distended, supported by bridges. In the front the keys are disposed, the long ones of which are the naturals, and the short ones the sharps and flats. These keys being pressed by the fingers, their inclosed extremities raise little upright oblong slips of wood called jacks, furnished with crow-quill plectrums, which strike the wires. The great advantage of the harpsichord beyond most other stringed instruments, consists in its capacity of sounding many notes at once, and forming those combinations, and performing those evolutions of harmony, which a single instrument cannot command. This instrument, called by the Italians *clave cymbala*, by the French *clavecin*, and in Latin *grave cymbalum*, is an improvement upon the clavicord, which was borrowed from the harp, and has for more than a century been in the highest esteem, and in the most general use, both public and private, throughout Europe; but since the invention of that fine instrument the grand piano-forte, its practice has considerably declined.

HARQUEBUSS, a piece of fire-arms, of the length of a musquet, usually cocked with a wheel. It carried a ball that weighed one ounce seven eighths.

HARRIER. See **CANIS**.

HARROW. See **HUSBANDRY**.

HART. See **CERVUS**.

HARTOGIA, a genus of the pentandria

order, in the monœcia class of plants; and in the natural method ranking under the 48th order, aggregatæ. The male calyx is pentaphyllous, the petals five; the female calyx triphyllous, with five petals, and five barren and five castrated stamina. There are three capsules; and the seeds are arillated, or inclosed in a deciduous case. There is one species, a tree of the Cape.

HARTSHORN, in chemistry. See **AMMONIA**.

HART'S HORNS, in pharmacy, the whole horns of the common male deer, as separated from the head, without farther preparation. See **HORNS**.

HASSELQUISTA, a genus of the class and order pentandria digynia. The cal. is radiated, in the disk male. Seeds in the circumference double, in the disk solitary. There are two species, herbs of Egypt.

HAT, a covering for the head, worn by the men in most parts of Europe. Those most in esteem are made of the pure hair of the castor or beaver; for they are also made of the hair or wool of divers other animals, and that by much the same process.

Hats are made either of wool, or hair of various animals, particularly of the castor, hare, rabbit, camel, &c. The process is much the same in all; for which reason we shall content ourselves with instancing that of the beaver. The skin of this animal is covered with two kinds of hair; the one long, stiff, glossy, and rather thin-set; this is what renders the skin or fur of so much value: the other is short, thick, and soft, which alone is used in hats. To tear off one of these kinds of hair, and cut the other, the hatters, or rather the women employed for that purpose, make use of two knives, a large one like a shoemaker's knife for the long hair, and a smaller, not unlike a vine-knife, where-with they shave or scrape off the shorter hair.

When the hair is off, they mix the stuff; to one-third of dry castor putting two-thirds of old coat, *i. e.* of hair which has been worn some time by the savages, and card the whole with cards, like those used in the woollen-manufactory, only finer; this done, they weigh it, and take more or less according to the size or thickness of the hat intended. The stuff is now laid on the hurdle, which is a square table, parallel to the horizon, having longitudinal chinks cut through it; on this hurdle, with an instrument called a bow, much like that of a violin, but larger, whose string is worked with a little bow-stick, and thus made to play on the furs, they fly and mix together, the dust and filth at the same time passing through the chinks. This they reckon one of the most difficult operations in the whole, on account of the justness required in the hand to make the stuff fall precisely together, and that it may be every where of the same thickness. In lieu of a bow, some hatters make use of a sieve or searce of hair, through which they pass the stuff.

After this manner they form gores, or two capades, of an oval form, ending in an acute angle at top; and with what stuff remains, they supply and strengthen them in places where they happen to be slenderer than ordinary; though it is to be remembered, that they designedly make them thicker in the brim, near the crown, than toward the circumference, or in the crown itself.

The capades thus finished, they go on to harden them into closer and more consistent flakes by pressing down a hardening skin or leather thereon; this done, they are carried to the bason, which is a sort of bench with an iron plate fitted in it, and a little fire underneath; upon which laying one of the hardened capades, sprinkled over with water, and a sort of mould being applied, the heat of the fire, with the water and pressing, embody the matter into a slight hairy sort of stuff or felt; after which, turning up the edges all round the mould, they lay it by, and thus proceed to the other: this finished, the next two are joined together, so as to meet in an angle at the top, and only form one conical cap, after the manner of a manican hippocratis, or jelly-bag.

The hat thus basoned, they remove it to a large kind of receiver or trough, resembling a mill-hopper, going sloping or narrowing down from the edge or rim to the bottom, which is a copper kettle filled with water and grounds, kept hot for that purpose. On the descent or sloping side, called the plank, the basoned hat, being first dipped in the kettle, is laid; and here they proceed to work it, by rolling and unrolling it again and again, one part after another, first with the hand, and then with a little wooden roller, taking care to dip it from time to time, till at length, by thus fulling and thickening it four or five hours, it is reduced to the extent or dimensions of the hat intended.

The hat thus wrought, they proceed to give it the proper form, which is done by laying the conical cap on a wooden block, of the intended size of the crown of the hat, and then tying it round with a packthread: after which, with a piece of iron or copper bent for that purpose, and called a stamper, they gradually beat or drive it down all round, till it has reached the bottom of the block, and thus is the crown formed; what remains at bottom below the string being the brim.

The hat being now set to dry, they proceed to singe it, by holding it over a flare of straw or the like; then it is pounced, or rubbed over with pumice, to take off the coarser knap; then rubbed over afresh with seal-skin to lay the knap a little finer; and lastly, carded with a fine card to raise the fine cotton, with which the hat is afterwards to appear.

Things thus far advanced, the hat is thus sent, upon its block, and tied about with a packthread as before, to be dyed. The dye being completed, the hat is returned to the hatter, who proceeds to dry it, by hanging it in the top or roof of a stove or oven, at the bottom of which is a charcoal fire; when dry, it is to be stiffened, which is done with melted glue or gum senegal, applied thereon by first smearing it, and beating it over with a brush, and then rubbing it with the hand. The next thing is to steam it on the steaming-bason, which is a little hearth or fire-place. When steamed sufficiently, and dried, they put it again on the block, and brush and iron it on a table or bench for the purpose, called the stall-board; this they perform with a sort of irons like those commonly used in ironing linen, and heated like them, which being rubbed over and over each part of the hat, with the assistance of the brush, smooths and gives it a gloss, which is the last operation;

nothing now remains but to clip the edges even with scissors, and sew a lining to the crown. For dyeing of hats, see DYEING.

A patent was granted in January, 1782, to Mr. Robert Golding, of Southwark, hat-dyer, for his method of dyeing, staining, and colouring, beaver hats green, or any other colour. The inventor directs the nap of the hat to be raised by means of a card, on the side intended to be dyed, and then boiled in alum argol. A thin paste should be made of flour, or clay, which is spread over every part that is not to be dyed, and then closed; or the hat may be previously pasted, and instead of being boiled, it should only be simmered in the same liquor. As soon as the paste is spread, plates of copper or other metal, shaped like a common funnel, are fixed over the paste, to prevent the dye from penetrating through. In this state the hat is immersed in the dye, till the colour is sufficiently fixed, when it is taken out, opened, and cleansed from the paste: but if any colouring particles have penetrated through the felt, they may be removed by rubbing them with a small quantity of spirit of salt, aquafortis, &c. The compounds employed in dyeing, are fustic, turmeric, ebony, saffron, alum, argol, indigo, and vitriol, with urine, or pearlash, at the option of the dyer; all which are used together, or separately, according to the colour required.

Mr. Dunnage, in 1794, obtained a patent for water-proof hats, in imitation of beaver. The articles he employs are similar to those commonly used for the making of hats, with which he mixes Bergam, Piedmont, or orgazine silk. These are dressed and worked in a peculiar manner; though we understand that hats thus prepared become heavy and oppressive to the wearer, while they acquire an ugly colour. The same manufacturer procured another patent in November, 1798, for a method of ventilating the crowns of hats. This invention consists in separating the top from the sides of the crown, so that the tip, or top crown, may be either raised or let down at pleasure, in order to admit the external air, or to exclude it from circulating in the crown of the hat. The whole contrivance is effected by means of springs, sliders, sockets, grooves, loops, and cases, which are connected with the top and side-crown: thus the admission or exclusion of atmospheric air in front, behind, or on either side, may be regulated accordingly. See Repertory, vol. iv. and x.

Another patent was granted for the same thing to Messrs. Walker and Alphey, in the year 1801.

Hats are also made for women's wear, of chips, straw, or cane, by platting, and sewing the plats together; beginning with the centre of the crown, and working round till the whole is finished. Hats for the same purpose are also woven, and made of horse-hair, silk, &c. There are few manufactures in the kingdom in which so little capital is wanted, or the knowledge of the art so soon acquired, as in that of straw-platting. One guinea is quite sufficient for the purchase of the machines and materials for employing one hundred persons for several months.

The straw is cut at the joints; and the outer covering being removed, it is sorted of equal sizes, and made up into bundles of

eight or ten inches in length, and a foot in circumference. They are then to be dipped in water, and shaken a little so as not to retain too much moisture; and then the bundles are to be placed on their edges, in a box which is sufficiently close to prevent the evaporation of smoke. In the middle of the box is an earthen dish containing brimstone broken in small pieces: this is set on fire, and the box covered over and kept in the open air several hours.

It will be the business of one person to split and select the straws for fifty others who are braiders. The splitting is done by a small machine made principally of wood. The straws, when split, are termed splints, of which each worker has a certain quantity: on one end is wrapped a linen cloth, and they are held under the arm, and drawn out as wanted.

Platters should be taught to use their second fingers and thumbs, instead of the fore-fingers, which are often required to assist in turning the splints, and very much facilitate the platting; and they should be cautioned against wetting the splints too much. Each platter should have a small linen work-bag, and a piece of pasteboard to roll the plat round. After five yards have been worked up, it should be wound about a piece of board half a yard wide, fastened at the top with yarn, and kept there several days to form it in a proper shape. Four of these parcels, or a score, is the measurement by which the plat is sold.

HACHEL, HACKLE, or HITCHEL, a tool with which flax and hemp are combed into fine hairs. It consists of long iron pins, or teeth, regularly set in a piece of board.

There are several sorts of hatchels, each finer than the other, with which flax and hemp are prepared for spinning.

HATCHES, in a ship, a kind of trap-doors between the main-mast and fore-mast, through which all goods of bulk are let down into the hold.

HATCHES also denote flood-gates set in a river, &c. to stop the current of the water; particularly certain dams or mounds made of rubbish, clay, or earth, to prevent the water that issues from the stream-works and tin-washes in Cornwall, from running into the fresh rivers.

HATCHING, the maturing fecundated eggs, whether by the incubation and warmth of the parent bird, or by artificial heat, so as to produce young chickens alive.

The art of hatching chickens by means of ovens has long been practised in Egypt; but it is there only known to the inhabitants of a single village named Berme, and to those who live at a small distance from it. Towards the beginning of autumn they scatter themselves all over the country, where each person among them is ready to undertake the management of an oven, each of which is of a different size, but in general they are capable of containing from forty to fourscore thousand eggs. The number of these ovens placed up and down the country is about three hundred and eighty-six, and they usually keep them working for about six months: as therepore each brood takes up in an oven, as under a hen, only twenty-one days, it is easy in every one of them to hatch eight different broods of chickens. Every Bermean is under

the obligation of delivering to the person who intrusts him with an oven, only two-thirds of as many chickens as there have been eggs put under his care; and he is a gainer by this bargain, as more than two-thirds of the eggs usually produce chickens. In order to make a calculation of the number of chickens yearly so hatched in Egypt, it has been supposed that only two-thirds of the eggs are hatched, and that each brood consists of at least thirty thousand chickens; and thus it would appear that the ovens of Egypt give life yearly to at least ninety-two millions six hundred and forty thousand of these animals.

This useful and advantageous method of hatching eggs has been employed in France, by the ingenious Mr. Reaumur, who, by a number of experiments, reduced the art to certain principles. He found by experience that the heat necessary for this purpose is nearly the same with that marked 32 on his thermometer, or that marked 96 on Fahrenheit's. This degree of heat is nearly that of the skin of the hen, and what is remarkable, of the skin of all other domestic fowls, and probably of all other kinds of birds. The degree of heat which brings about the development of the cygnet, the gosling, and the turkey-pout, is the same as that which fits for hatching the canary-songster, and, in all probability, the smallest humming-bird: the difference is only in the time during which this heat ought to be communicated to the eggs of different birds: it will bring the canary-bird to perfection in eleven or twelve days, while the turkey-pout will require twenty-seven or twenty-eight.

Mr. Reaumur invented a sort of low boxes, without bottoms, and lined with furs. These, which he calls artificial parents, not only shelter the chickens from the injuries of the air, but afford a kindly warmth, so that they presently take the benefit of their shelter as readily as they would have done under the wings of a hen. After hatching, it will be necessary to keep the chickens for some time in a room artfully heated, and furnished with these boxes; but afterwards they may be safely exposed to the air in the court-yard, in which it may not be amiss to place one of these artificial parents to shelter them if there should be occasion for it.

As to the manner of feeding the young brood, they are generally a whole day after being hatched before they take any food at all; and then a few crumbs of bread may be given them for a day or two, after which they will begin to pick up insects and grass for themselves. But to save the trouble of attending them, capons may be taught to watch them in the same manner as hens do. Mr. Reaumur assures us that he has seen above two hundred chickens at once, all led about and defended only by three or four such capons. Nay, cocks may be taught to perform the same office, which they, as well as the capons, will continue to do all their lives after.

HATCHING, or *Haching*, in designing, &c. the making of lines with a pen, pencil, graver, or the like; and the intersecting or going across those lines with others drawn a contrary way, is called counter-hatching. The depths and shadows of draughts are usually formed by hatching.

HATTOCK, a shock of corn containing

twelve sheaves: others make it only three sheaves laid together.

HAUL, or **HALE**, an expression peculiar to seamen, implying to pull a single rope, without the assistance of blocks or other such mechanical powers. To haul the wind, is to direct the ship's course nearer to that point of the compass from which the wind arises.

HAUTBOY, a musical instrument of the wind-kind, shaped much like the flute, only that it spreads and widens towards the bottom, and is sounded through a reed. The treble is two feet long; the tenor goes a fifth lower, when blown open: it has only eight holes; but the bass, which is five feet long, has eleven.

HAWK. See **FALCO**.

HAWKERS and **PEDLARS**, are such dealers or itinerary petty chapmen as travel to different fairs or towns with goods or wares, and are placed under the controul of commissioners, by whom they are licensed for that purpose pursuant to stat. 8 and 9 W. III. c. 25. and 29 Geo. III. c. 26. Traders in linen and woollen manufactories sending their goods to markets and fairs, and selling them by wholesale; manufacturers selling their own manufactures, and makers and sellers of English bone-lace going from house to house, &c. are excepted out of the acts, and not to be taken as hawkers.

HAWKING. See **FALCONRY**.

HAWSER, in the sea-language, a large rope, or a kind of small cable, serving for various uses aboard a ship, as to fasten the main and fore shrouds, to warp a ship as she lies at anchor, and wind her up by a capstern, &c. The hawser of a man of war may serve for a cable to the sheet-anchor of a small ship.

HAWSES, in a ship, are two large holes under the bow, through which the cables run when she lies at anchor. Thus the hawse-pieces are the large pieces of timber in which these holes are made. Hawse-bags, are bags of canvas made tapering, and stuffed full of oakum; which are generally allowed small ships, to prevent the sea from washing in at these holes: and hawse-plugs are plugs to stop the hawses, to prevent the water from washing into the manger.

There are also some terms in the sea-language that have an immediate relation to the hawses. Thus a bold hawse, is when the holes are high above the water. Fresh the hawse, or veer out more cable, is used when part of the cable that lies in the hawse is fretted or chafed, and it is ordered that more cable may be veered out, so that another part of it may rest in the hawses. Fresh the hawse, that is, lay new pieces upon the cable in the hawses, to preserve it from fretting. Burning in the hawse, is when the cables endure a violent stress. Clearing the hawses, is disentangling two cables that come through different hawses. To ride hawse-full, is when in stress of weather the ship falls with her head deep in the sea, so that the water runs in at the hawses.

HAY, any kind of grass, cut and dried, for the food of cattle. See **HUSBANDRY**.

HAZARD: a game on dice, without tables, is very properly so called, since it speedily makes a man, or undoes him.

It is played with only two dice; and as

many may play it as can stand round the largest round table.

Two things are chiefly to be observed, viz. main and chance; the latter belonging to the caster, and the former, or main, to the other gamblers. There can be no main thrown above nine, nor under five; so that five, six, seven, eight, and nine, are the only mains flung at hazard. Chances and nicks are from four to ten: thus four is a chance to nine, five to eight, six to seven, seven to six, eight to five; and nine and ten a chance to five, six, seven, and eight: in short, four, five, six, seven, eight, nine, and ten, are chances to any main, if any of these nick it not. Now nicks are either when the chance is the same with the main, as five and five, or the like; or six and twelve, seven and eleven, eight and twelve. Here observe, that twelve is out to nine, seven, and five; eleven is out to nine, eight, six, and five; and ames-ace and deuce-ace are out to all mains whatever.

But to illustrate this game by a few examples: Suppose the main to be seven, and the caster throws five, which is his chance; he then throws again, and if five turn up, he wins all the money set him; but if seven is thrown, he must pay as much money as there is on the board: again, if seven is the main, and the caster throws eleven, or a nick, he sweeps away all the money on the table; but if he throws a chance, as in the first case, he must throw again: lastly, if seven is the main, and the caster throws ames-ace, deuce-ace, or twelve, he is out; but if he throws from four to ten, he has a chance; though they are accounted the worst chances on the dice, as seven is reputed the best and easiest main to be flung. Four and five are bad throws (the former of which being called by the tribe of niggers little dick-fisher), as having only two chances, viz. trey-ace and two deuces, or trey-deuce and quatre-ace: whereas seven has three chances, viz. cinque-deuce, sice-ace, and quatre-trey. Nine and ten are in the like condition with four and five, having only two chances. Six and eight have indeed the same number of chances with seven, viz. three; but experienced gamblers nevertheless prefer the seven, by reason of the difficulty to throw the doublets, two quarters, or two treys. It is also the opinion of most, that at the first throw the caster has the worst of it. On the whole, hazard is certainly one of the most bewitching and ruinous games played on the dice. Happy, therefore, the man who either never heard of it, or who has resolution enough to leave it off in time.

HAZEL. See **CORYLUS**.

HEAD. See **ANATOMY**.

HEAD. See **ARCHITECTURE**.

HEAD, in heraldry. The heads of men, beasts, or birds, are very frequent in armoury; and borne either full-faced, looking forward, or side-faced in profile, when only one half of the face appears, which differences ought to be mentioned in blazoning, to avoid mistakes; as a head, or heads fronting; or a head, or heads side-faced, or in profile: thus, vert, a chevron gules, between three turks' heads couped side-faced proper, is borne by the name of Smith. And again, or, a cross gules, between four blackmoors' heads, couped at the shoulders proper, is borne by the name Juxon. As the head is the principal part of the body, so it is of course the noblest bearing.

Among medalists, the different heads on ancient coins, are distinguished by the different dresses. See MEDAL.

In the imperial medals, where the head is quite bare, it is usually a sign the person was not an emperor, but one of the children of an emperor, the presumptive heir of the empire. The heads which are covered, are either covered with a diadem, or a crown, or a simple cork, or a veil, with some other foreign covering, whereof the diadem is the most antient. The heads of deities are distinguished by some special symbol.

HEAD-ACHE. See MEDICINE.

HEADBORROW, or HEADBOROUGH, the chief of the frankpledge, and he that had the principal government of them within his own pledge. And as he was called head-borrow, so was he called burrowhead, burs-holder, thirdborrow, tithingman, chiefpledge, or borrow-elder, according to the diversity of terms in several places. The same officer is now occasionally called a constable. The headborough was the chief of the ten pledges: the other nine were called hard-boroughs, or inferior pledges.

HEAD-LINES, in a ship, those ropes of all sails which are next to the yards, and by which the sails are made fast to the yard.

HEAD-SEA, is when a great wave or billow of the sea comes right ahead of the ship, as she is in her course.

HEAD-SAILS, in a ship, those which belong to the fore-mast and boltsprit: for it is by these that the head of the ship is governed, and made to fall off and keep out of the wind; and these in quarter-winds are the chief drawing sails.

HEAD of a ship, or other vessel, is the prow, or that part which goes foremost.

Dragon's HEAD, in astronomy, &c. is the ascending node of the moon, or other planet. See NODE.

HEARING, the sense whereby we perceive sounds. See ANATOMY, PHYSIOLOGY, and SOUNDS.

HEARSAY, is generally not to be admitted as evidence; for no evidence is to be allowed but what is upon oath; for if the first speech was without oath, another oath that there was such speech, makes it no more than a bare speaking, and so of no value in a court of justice; and besides, the adverse party has no opportunity of a cross-examination; and if the witness is living, what he has been heard to say is not the best evidence that the nature of the thing will admit. But in some cases hearsay evidence is allowed to be admissible; as to prove who was a man's grandfather when he married, what children he had, and the like; of which it is not reasonable to presume that there is better evidence. So in questions of prescription, it is allowed to give hearsay evidence, in order to prove general reputation; as where the issue was of a right to a way over the plaintiff's close, the defendant was admitted to give evidence of a conversation between persons not interested, then dead, wherein the right to the way was agreed. Theory of Evid. III. See EVIDENCE.

HEARSE. See HIND.

HEART. See ANATOMY.

HEAT, in physiology. See CALORIC.

HEAT, Animal. See RESPIRATION.

HEAT, in geography, the diversity of

the heat of climates and seasons arising chiefly from the different angles under which the sun's rays strike upon the surface of the earth. Dr. Halley gives a mathematical computation of the effect of the sun under the different seasons and climates. Let it, however, be considered, that the different degrees of heat and cold in different places depend in a very great measure upon the accidents of situation, with regard to mountains and valleys, and the soil. The first greatly helps to chill the air by the winds which come over them, and which blow in eddies through the levels beyond; and mountains, sometimes turning a concave side to the sun, have the effects of a burning mirror upon the subject plain; and the like effect is sometimes had from the convex parts of clouds, either by refraction, or reflection. As to soils, a stony, sandy, or chalky earth, it is known, reflects most of the sun's rays into the air again, and retains but few, by which means a considerable accession of heat is derived to the air; as, on the contrary, black loose soils absorb most of the rays, and return few into the air, so that the ground is much the hotter.

The following table of the heat of different climates is computed for every tenth degree of latitude, to the equinoctial and tropical sun; by which an estimate may be made of the intermediate degrees.

| Lat. | Sun in
$\gamma \approx$ | Sun in
ϖ | Sun in
ψ |
|------|----------------------------|--------------------|------------------|
| 0 | 20000 | 18341 | 18341 |
| 10 | 19696 | 20290 | 15854 |
| 20 | 18797 | 21737 | 13166 |
| 30 | 17321 | 22651 | 10124 |
| 40 | 15321 | 23048 | 6944 |
| 50 | 12855 | 22991 | 3798 |
| 60 | 10000 | 22773 | 1075 |
| 70 | 6840 | 23543 | 000 |
| 80 | 3473 | 24673 | 000 |
| 90 | 0000 | 25055 | 000 |

Hence are deducible the following corollaries. 1. That the equinoctial heat, when the sun becomes vertical, is as twice the square of the radius, which may be proposed as a standard to compare with in all other cases. 2. That under the equinoctial, the heat is as the sine of the sun's declination. 3. That in the frigid zones, where the sun sets not, the heat is as the circumference of a circle into the sine of the altitude at 6; and consequently that in the same latitude these aggregates of warmth are as the sine of the sun's declination; and at the same declination of the sun, they are as the sines of the latitudes into the signs of the declination. 4. That the equinoctial day's heat is every where as the cosine of the latitude. 5. In all places where the sun sets, the difference between the summer and winter heats, when the declinations are contrary, is equal to a circle into the sine of the altitude at 6 in the summer parallel; and consequently these differences are as the sine of the latitude into or multiplied by the sines of declination. 6. From the foregoing table, it appears that the tropical sun under the equinoctial, has of all others the least force. Under the pole, it is greater than any other day's heat whatever; being to that of the equinoctial as 5 to 4.

HEATH. See ERICA.

HEBENSTRETIA, a genus of the angiospermia order, in the didynamia class of

plants; and in the natural method ranking under the 48th order, aggregatae. The calyx is emarginated, and divided below; the corolla unilabiate; the lip rising upwards, and quadrifid; the capsule dispermous; the stamina inserted into the margin of the limb of the corolla. There are six species, herbs of the Cape.

HECATOMBÆON, in ancient chronology, the first month of the Athenian year, consisting of thirty days, and answering to the latter part of our June and beginning of July.

HECTIC, or HECTIC FEVER. See MEDICINE.

HEDERA, Ivy, a genus of the monogynia order, in the pentandria class of plants; and in the natural method giving name to the 46th order, hederaceae. There are five oblong petals; the berry is pentaspermous, girt by the calyx. There are six species; the most remarkable are: 1. The helix, or common ivy, which grows naturally in many parts of Britain; and, where it meets with any support, will rise to a great height, sending out roots on every side, which strike into the joints of walls or the bark of trees. If there is no support, they trail on the ground, and take root all their length, so that they closely cover the surface, and are difficult to eradicate. While these stalks are fixed to any support, or trail upon the ground, they are slender and flexible; but when they have reached to the top of their support, they shorten and become woody, forming themselves into large bushy heads; and their leaves are larger, more of an oval shape, and not divided into lobes like the lower leaves, so that it has a quite different appearance. There are two varieties of this species; one with silver-striped leaves, the other with yellowish leaves on the tops of the branches; and these are sometimes admitted into gardens. 2. The quinquifolia, or Virginia creeper, is a native of all the northern parts of America. It was first brought to Europe from Canada; and has been long cultivated in the British gardens, chiefly to plant against walls or buildings to cover them: which these plants will do in a short time; for they will shoot almost twenty feet in one year, and will mount up to the top of the highest building; but as the leaves fall off in autumn, the plants make but an indifferent appearance in winter, and therefore are proper only for such situations as will not admit of better plants; for this will thrive in the midst of cities, and is not injured by the smoke or the closeness of the air.

The roots of the ivy are used by leather-cutters to whet their knives upon. Apricots and peaches covered with ivy during the month of February, have been observed to bear fruit plentifully. The leaves have a nauseous taste; Haller says, they are given to children in Germany, as a specific for the atrophy. The common people of England apply them to issues; and an ointment made from them is in great esteem among the Highlanders of Scotland as a ready cure for burns. The berries have a little acidity. In warm climates, a resinous juice exudes from the stalks, which is said to be a powerful solvent, and an excellent ingredient in plasters and ointments. Horses and sheep eat the plant; goats and cows refuse it.

HEDGE-BREAKERS, by 43 Eliz. c. 7. shall pay such damages as a justice of the peace shall think fit; and on nonpayment shall be whipped. And by 15 Car. II. c. 6. the constable may apprehend a person suspected, and by warrant of a justice, may search his houses and other places; and if any hedge-wood shall be found, and he shall not give a good account how he came by the same, he shall be adjudged the stealer thereof.

HEDGES. See **HUSBANDRY**.

HEDWIGEN, a genus of the octandria monogynia class and order. The cal. is four-toothed; the cor. four-cleft; style none; caps. tricoceous; seed a nut. There is one species, a tree of St. Domingo.

HEDYCARYA, a genus of the icosandria order, in the diœcia class of plants. The calyx of the male is cleft in eight or ten parts; there is no corolla, nor are there any filaments; the antheræ are in the bottom of the calyx, four-furrowed, and bearded at top. The calyx and corolla of the female are as in the male; the germs pedicellated; the nuts pedicellated and monospermous. There is one species, a tree of Guiana.

HEDYCREA, a genus of the class and order pentandria monogynia. The cal. is one-leafed, hemispherical, five-toothed: cor. none: drupe oval, one-celled: nect. ovate, covered with fibres, one-celled; shell hard. There is one species, a tree of Guiana.

HEDYOSMUM, a genus of the class and order monœcia polyandria. The male is an ament with anthers; no cor. perianth. or filaments. The female has cal. three-toothed; cor. none; style one, three-cornered; berry three-cornered, one-seeded. There are two species, shrubs of Jamaica.

HEDYOTIS, a genus of the monogynia order, in the tetrandria class of plants; and in the natural method ranking under the 47th order, stellatæ. The corolla is monopetalous and funnel-shaped; the capsule is bilocular, polyspermous, inferior. There are eight species, herbs of Ceylon, &c.

HEDYPNOIS, a genus of the class and order syngenesia polygamia æqualis. The cal. is calyced, with short scales; seeds crowned with the calycle; recept. naked, hollow-dotted.

HEDYSARUM, a genus of the decandria order, in the diadelphica class of plants; and in the natural method ranking under the 32d order, papilionaceæ. The carina of the corolla is transversely obtuse; the seed-vessel a legumen with monospermous joints. There are 90 species of this plant, of which the most remarkable are: 1. The gyrans, or sensitive hedysarum, a native of the East Indies, where it is called burrum chundalli. It arrives at the height of four feet, and in autumn produces bunches of yellow flowers. The root is annual or biennial. It is a trifolious plant, and the lateral leaves are smaller than those at the end, and all day long they are in constant motion without any external impulse. They move up and down, and circularly. This last motion is performed by the twisting of the footstalks; and while the one leaf is rising, its associate is generally descending. The motion downwards is quicker and more irregular than the motion upwards, which is steady and uniform. These motions are observable for the space of 24 hours in the leaves of a branch which is lop-

ped off from the shrub, if it is kept in water. If from any obstacle the motion is retarded, upon the removal of that obstacle it is resumed with a greater degree of velocity. 2. The coronarium, or common biennial French honeysuckle, has large deeply-striking biennial roots; upright, hollow, smooth, very branchy stalks, three or four feet high, with pinnated leaves; and from between the leaves proceed long spikes of beautiful red flowers, succeeded by jointed seed-pods. The first species, being a native of hot climates, requires the common culture of tender exotics; the second is easily raised from a seed in any of the common borders, and is very ornamental.

HEEL. See **ANATO Y**.

HEEL, in the sea-language. If a ship leans on one side, whether she is aground or afloat, then it is said she heels astarboard, or aport; or that she heels offwards, or to the shore; that is, inclines more to one side than to another.

HEGIRA, in chronology, a celebrated epocha among the Mahometans. The event which gave rise to this epocha was the flight of Mahomet from Mecca, with his new proselytes, to avoid the persecution of the Koraischites; who, being then most powerful in the city, could not bear that Mahomet should abolish idolatry, and establish his new religion. This flight happened in the fourteenth year after Mahomet had commenced prophet: he retired to Medina, which he made the place of his residence.

HEIGHT, in geometry, is a perpendicular let fall from the vertex, or top, of any right-lined figure, upon the base or side subtending it. It is likewise the perpendicular height of any object above the horizon; and is found several ways: by two staffs, a plain mirror with the quadrant, theodolite, or some graduated instrument, &c.

The measuring of heights or distances is of two kinds: when the place or object is accessible, as when you can approach to its bottom; or inaccessible, when it cannot be approached.

PROB. I. To measure an accessible height AB, by means of two staffs. See plate Miscel. fig. 111.

Let there be placed perpendicularly in the ground, a longer staff DE, likewise a shorter one FG, so that the observer may see A, the top of the height to be measured, over the ends D, F, of the two staffs; let FH and DC, parallel to the horizon, meet DE and AB in H and C; then the triangles FHD, DCA, shall be equiangular; for the angles at C and H are right ones: likewise the angle A is equal to FDH; wherefore the remaining angles are also equal. Therefore, as FH, the distance of the two staffs, is to HD, the excess of the longer staff above the shorter; so is DC, the distance of the longer staff from the tower, to CA, the excess of the height of the tower above the longer staff; and thence CA will be found by the rule of three. To which if the length DE be added, you will have the whole height of the tower BA.

Schol. um. Another method may be occasionally contrived for measuring an accessible height; as by the given length of the shadow BD (fig. 112), I find out the height AB: for let there be erected a staff CE, perpendicularly, producing the shadow EF; then it will be as EF, the shadow of the staff, is to EC, the staff itself; so is BD, the shadow of the tower, to BA, the height. Though the plane on which the shadow of the tower falls, be not parallel to the horizon, yet if the staff be erected in the same plane, the rule will be the same.

PROB. II. To measure an accessible height by means of a plain mirror.

Let AB (fig. 113) be the height to be measured; let the mirror be placed at C, in the horizontal plane BD, at a known distance BC: let the observer go back to D, till he see the image of the summit in the mirror, at a certain point of it, which he must diligently mark; and let DE be the height of the observer's eye. The triangles ABC and EDC, are equiangular; for the angles at D and B are right angles; and ACB, ECD, are equal, being the angles of incidence and reflection of the ray AC; wherefore the remaining angles at A and E, are also equal. Therefore it will be, as CD is to DE, so is CB to BA.

The observer will be more exact, if, at the point D, a staff be placed in the ground perpendicularly, over the top of which the observer may see a point of the glass exactly in a line betwixt him and the tower.

In place of a mirror may be used the surface of water, which naturally becomes parallel to the horizon.

PROB. III. To measure an accessible height by the geometrical quadrant, theodolite, &c.

Let the angle C (fig. 114) be found. Then in the triangle ABC, right-angled at B (BC being supposed the horizontal distance of the observer from the tower), having the angle C, and the side BC, the required height will be found by the first case of plan trigonometry. Thus, suppose the angle C. $37^{\circ} 24'$, and the horizontal distance, BC, 116, then the proportion will be as R : T. $\angle C :: CB : BA$, the height.

| | | | |
|---------------------------------------|---|---|---------|
| The tangent altitude $37^{\circ} 24'$ | - | - | 9.88341 |
| Log. CB 116 | - | - | 2.06446 |

| | | |
|--------|---|----------|
| Added | - | 11.94787 |
| Radius | - | 10.00000 |

| | | |
|-------------------------|-------|---------|
| Height of the object AB | 88.69 | 1.94787 |
|-------------------------|-------|---------|

Supposing the observation made on the top of the tower, and the height of the tower to be known, to find the distance of any object on the plane below; it is only the converse of the former case.

You may also, having the base and angles, easily find the hypotenuse AC, or how far it is from the top of the tower to the station, by the second case of right-angled triangles: and it is useful in many cases.

PROB. IV. To measure an inaccessible height by the geometrical quadrant, &c. at two stations.

Let the angle ACB be observed (fig. 115); let the observer go from C, to the second station D, in the right line BCD; and after measuring this distance CD, take the angle ADC likewise with the quadrant. Then in the triangle ACD, which is formed by the two visual rays AD, AC, and the distance of the two stations D and C, there is given the angle ADC, with the angle ACD, because the angle ACB was given before; therefore the remaining angle CAD is given likewise. But the distance of the stations C and D is also given; therefore by the second case of oblique-angled trigonometry, the side AC will be found. Wherefore, in the right-angled triangle ABC, all the angles and the hypotenuse AC are given; consequently by the third case of plain trigonometry, the height sought, AB, may be found; as also the distance of the station C, from AB, the perpendicular within the hill or inaccessible height.

Example. Suppose the angle at C $45^{\circ} 30'$, and the angle at D $32^{\circ} 12'$, and the distance CD, betwixt the two stations, 112 feet; then the angle DAC will be $11^{\circ} 18'$, and the angle CAB $46^{\circ} 30'$. Hence for CA, the proportion will be as S. $\angle DAC :: DC :: S. \angle D :: CA$.

| | | | |
|--------------------------------|---|---|----------|
| The log. DC 112 | - | - | 2.04922 |
| Sine $\angle D 32^{\circ} 12'$ | - | - | 9.72663 |
| Added | - | - | 11.77585 |
| S. $\angle DAC 11^{\circ} 18'$ | - | - | 9.29214 |
| CA = 304.6 | - | - | 2.48371 |

Then for AB, the height of the object, it will be as R : S. $\angle ACB :: CA : AB$.

| | | | |
|------------------------------------|---|---|----------|
| As radius | - | - | 10.00000 |
| is to the sine of $43^{\circ} 30'$ | - | - | 9.83781 |
| so is CA 304.6 | - | - | 2.48371 |
| to AB 209.7 | - | - | 2.32152 |

Lastly, for CB, the distance of the object from the nearest station, it will be as R : S. $\angle CAB :: CA : BC$.

| | | | |
|--|---|---|----------|
| As radius | - | - | 10.00000 |
| is to the sine of $CAB 46^{\circ} 30'$ | - | - | 9.86056 |
| so is CA 304.6 | - | - | 2.48371 |
| to BC 221 | - | - | 2.34427 |

If the height of the tower is wanted, the angle BCF (fig. 116) may be found with the quadrant, which being taken from the angle ACB already known, the angle ACF will remain; but the angle FAC was known before; therefore the remaining angle AFC will be known. But the side AC was supposed found by the last problem; therefore in the triangle AFC, all the angles, and one of the sides AC, being known, AF the height of the tower above the hill may be found by trigonometry.

PROB. V. To measure the distance of two places A and B, of which one, A, is accessible, by the theodolite, fig. 117.

Let there be erected at two points, A and C (sufficiently distant), visible signs; then let the two angles BAC, BCA, be taken by the theodolite. Let the distance of the stations A and C be measured with a chain. Then the third angle being known, and the side AC; therefore, by the second case of oblique trigonometry, the distance required AB will be found.

PROB. VI. To measure by the theodolite, &c. the distance of two places, neither of which is accessible, fig. 118.

Let two stations C and D be chosen, from each of which the places may be seen whose distance is sought. Let the angles ACD, BCD, and likewise the angles BDC, BDA, CDA, be measured by the theodolite, &c. and the distance of the stations C and D be measured by a chain, or, if necessary, by the last problem. Now in the triangle ACD, there are given two angles ACD and ADC; therefore the third CAD is likewise given: moreover the side CD is given; therefore by the second case of oblique trigonometry, the side AD will be found. After the same manner, in the triangle BCD, from all the angles, and one side CD given, the side BD is found. Wherefore, in the triangle ADB, from the given sides DA and DB, and the angle ADB contained by them, the side AB (the distance sought) is found too by the fourth case of oblique-angled trigonometry. Note, that it is not necessary that the points A, B, C, and D, be in one plane, and that any triangle is in one plane.

HEIR, is he to whom lands, tenements, or hereditaments, by the act of God and right of blood, descend of some estate of inheritance. Co. Lit. 7. b.

HEIR apparent. Here we must observe, that no person can be heir until the death of his ancestor; yet in common parlance, he who stands nearest in degree of kindred to the ancestor, is called even in his life-time, heir apparent. Co. Lit. 8. n. The law also takes notice of an heir apparent, so far as to allow the father to bring an action of trespass for taking away his son and heir, the father

being guardian by nature to his son, where any lands descended to him. Co. Lit. 37.

Heir-general: the heir-general, or heir at common law, is he who after his father's or ancestor's death has a right to, and is introduced into, all his land, tenements, and hereditaments; but he must be of the whole blood, not a bastard, alien, &c. None but the heir-general, according to the course of the common law, can be heir to a warranty, or sue an appeal of the death of his ancestors. Co. Lit. 14.

Customary heir: a custom in particular places varying the rules of descent at common law is good; such is the custom of gavelkind, by which all the sons shall inherit, and make but one heir to their ancestor; but the general custom of gavelkind lands extends to sons only; but a special custom, that if one brother dies without issue, all his brothers may inherit, is good. Co. Lit. 140. a.

To prevent the wrong and injury to creditors by the alienation of the lands descended, &c. by 3 and 4 W. & M. c. 14. it is enacted, that in all cases where any heir at law shall be liable to pay the debt of his ancestor, in regard of any lands, tenements, or hereditaments descending to him, and shall sell, alien, and make over, the same before any action brought or process sued out against him, such heir at law shall be answerable for such debt or debts in action or actions of debt to the value of the said land so by him sold, alienated, or made over; in which case all creditors shall be preferred, as in actions against executors and administrators: and such execution shall be taken out upon any judgment or judgments so obtained against such heirs, to the value of the said land, as if the same were his own proper debts; saving that the lands, tenements, and hereditaments, bona fide aliened before the action brought, shall not be liable to such execution. Provided, that where any action of debt upon any specialty, is brought against any heir, he may plead *riens per descent* at the time of the original writ brought, or the bill filed against him; any thing therein contained to the contrary notwithstanding. And the plaintiff in such action may reply, that he had lands, tenements, or hereditaments, from his ancestor before the original writ brought, or the bill filed; and if upon issue joined thereupon, it is found for the plaintiff, the jury shall inquire of the value of the lands, tenements, or hereditaments so descended, and thereupon judgment shall be given, and execution shall be awarded as aforesaid; but if judgment is given against such heir, by confession of the action with the assets descended, or upon demurrer, or *nihil dixit*, it shall be for the debt and damages, without any writ to enquire of the lands, tenements, or hereditaments, so descended.

Before this statute, if the ancestor had devised away the lands, a creditor by specialty had no remedy, either against the heir or devisee. Abr. Eq. 149.

But by the said statute, it is enacted that all wills and testaments, limitations, dispositions, or appointments, of or concerning any manors, messuages, lands, tenements, or hereditaments, or of any rent, profit, term, or charge out of the same, whereof any person at the time of his decease shall be seized in fee simple, possession, reversion, or remain-

der, or have power to dispose of the same by his last will and testament, shall be deemed and taken only against such creditor as aforesaid, his heirs, successors, executors, administrators, and assigns, and every of them, to be fraudulent, and clearly, absolutely, and utterly void, frustrate, and of none effect; any pretence, colour, feigned or presumed consideration, or any other matter or thing, to the contrary notwithstanding.

And for the means, that such creditors may be enabled to recover their said debts, it is farther enacted, that in the cases before-mentioned, every such creditor shall and may maintain his action of debt, upon his said bonds and specialties, against the heir at law of such obligor, and such devisee and devisees jointly, by virtue of this act; and such devisee and devisees shall be liable and chargeable for a false plea by him or them pleaded, in the same manner as any heir should have been for false plea by him pleaded, or for not confessing the lands or tenements to him descended.

Provided, that where there has been or shall be any limitation or appointment, devise or disposition, of any manors, messuages, lands, tenements, or hereditaments, for the raising or payment of any real or just debt, or any portion, sum, or sums of money, for any child or children of any person, other than the heir at law, in pursuance of any marriage-contract or agreement in writing bona fide made before such marriage; the same and every of them shall be in full force, and the same manors, &c. may be holden and enjoyed by every such person, his heirs, executors, administrators, and assigns, for whom the said limitation, appointment, devise, or disposition was made, and by his trustee, his heirs, executors, administrators, and assigns, for such estate or interest as shall be so limited or appointed, devised, or disposed, until such debt or debts, portion or portions, shall be raised, paid, and satisfied; any thing contained in this act to the contrary notwithstanding.

And it is further enacted by the said statute, that all and every devisee and devisees made liable by this act, shall be liable and chargeable in the same manner as the heir at law, by force of this act, notwithstanding the lands, tenements, and hereditaments to him or them devised, shall be aliened before the action brought.

In the construction of this statute it has been holden, that though a man is prevented thereby from defeating his creditors by will, yet any settlement or disposition he shall make in his life-time of his lands, whether voluntary or not, will be good against bond creditors; for that was not provided against by the statute, which only took care to secure such creditors from any imposition which might be supposed in a man's last sickness; but if he gave away his estate in his life-time, this prevented the descent of so much to the heir, and consequently took away their remedy against him, who was only liable in respect of the lands descended; and as a bond is no lien whatsoever on the lands in the hands of the obligor, much less can it be so when they are given away to a stranger. Abr. Eq. 149.

HEIRESS, is a female heir to a person having an estate of inheritance of lands. If there are more than one, they are called co-

heiresses, or rather, in legal expression, co-heirs. The offence of stealing an heiress is founded on the statute 3 Hen. VII. c. 2. which enacts, that if any man shall, for lucre, take any woman, being maid, widow, or wife, and having substance either in goods or lands, or being heir apparent to her ancestor, contrary to her will, and afterwards she be married to such misdoer, or by his consent to another, or defiled; he, his procurors, and abettors, and such as knowingly receive such woman, shall be deemed principal felons; and by 39 Eliz. c. 9. the benefit of clergy is taken away from principals, procurors, and accessories before. And it is not material whether a woman so taken contrary to her will, be at last married or defiled with her own consent or not, if she were under the force at the time.

HEIR-LOOMS, are such goods and personal chattles as, contrary to the nature of chattles, shall go by special custom to the heir, along with the inheritance, and not the executor of the last proprietor.

HEISTERIA, a genus of the monogynia order, in the decandria class of plants, and in the natural method ranking under the 12th order, holoraceæ. The calyx is quinquefid, the petals five; the fruit is a plum on a very large-coloured calyx. There is one species, a tree of Martinico.

HELENIUM, *bastard sun-flower*, a genus of the polygamia superflua order, in the syngenesia class of plants, and in the natural method ranking under the 49th order, compositæ. The receptacle is naked in the middle; under the radius, paleaceous; the pappus consists of five short awns; the calyx is simple and multipartite; the florets of the radius semitrid. The species are: 1. The autumnale, with spear-shaped narrow leaves. 2. The pubescens, with pointed, spear-shaped, sawed leaves. Both these are natives of North America, where they grow wild in great plenty. They rise to the height of seven or eight feet in good ground. The roots, when large, send up a great number of stalks, which branch toward the top; the upper part of the stalk sustains one yellow flower, shaped like the sun-flower, but much smaller, having long rays, which are jagged pretty deep into four or five segments. These plants may be propagated by seeds, or by parting their roots; the latter is generally practised in this country. The best season to transplant and part the old roots is in October, when their leaves are past, or in the beginning of March just before they begin to shoot. They delight in a soil rather moist than dry, provided it is not too strong, or does not hold the wet in winter.

HELEPOLIS, in the antient art of war, a machine for battering down the walls of a place besieged, the invention of which is ascribed to Demetrius, the Poliorcete. Diodorus Siculus says, that each side of the helepoleis was 405 cubits broad, and 90 in height; that it had nine stages, and was carried on four strong solid wheels eight cubits in diameter; that it was armed with large battering-rams, and had two roofs capable of supporting them; that in the lower stages there were different sorts of engines for casting stones; and in the middle they had large catapultas for lancing arrows, and smaller in those above, with a number of expert men for working all these machines.

HELIAEA, in Grecian antiquity, was the greatest and most frequented court in Athens, for the trial of civil affairs. The judges who sat in it were at least fifty, but the more usual number was either two or five hundred. When causes of great moment were to be tried, it was customary to call in the judges of the other courts: sometimes a thousand were called in, and then two courts are said to have been joined: sometimes fifteen hundred or two thousand were called in, and then three or four courts met together. They had cognizance of civil affairs of the greatest weight and importance, and were not permitted to give judgment till they had taken a solemn oath to do it with impartiality, and to give sentence according to the laws, &c.

HELIACAL, in astronomy, a term applied to the rising or setting of the stars, or, more strictly speaking, to their emersion out of and immersion into the rays and superior splendor of the sun.

A star is said to rise heliacally, when after having been in conjunction with the sun, and on that account invisible, it comes to be at such a distance from him, as to be seen in the morning before sun-rising; the sun, by his apparent motion, receding from the star towards the east: on the contrary, the heliacal setting is when the sun approachess so near a star as to hide it with his beams, which prevent the fainter light of the star from being perceived, so that the terms apparition and occultation would be more proper than rising and setting.

All the fixed stars in the zodiac, as also the superior planets, Mars, Jupiter, and Saturn, rise heliacally in the morning, a little before sun-rising, and a few days after they have set cosmically. Again, they set heliacally in the evening, a short time before their achronycal setting. But the moon, whose motion eastward is always quicker than the apparent motion of the sun, rises heliacally in the evening, after the new moon, and sets heliacally in the morning, when old and approaching to a conjunction with the sun.

The inferior planets, Venus and Mercury, which sometimes seem to go westward from the sun, and sometimes again have a quicker motion eastward, rise heliacally in the morning, when they are retrograde; but when direct in their motions, they rise heliacally in the evening. The heliacal rising or setting of the moon happens when she is 17° degrees distant from the sun; but for the other planets 20° are required; and for the fixed stars more or less according to their magnitude.

HELIANTHUS, *the great sun-flower*, a genus of the polygamia frustanea order, in the syngenesia class of plants, and in the natural method ranking under the 49th order, compositæ. The receptacle is paleaceous and plane; the pappus diphyllous; the calyx imbricated; the scales standing a little out at the tops. There are 12 species, most of which are now very common in our gardens, though all of them are natives of America. They are all very hardy, and will thrive in almost any soil or situation. They may be propagated either by seeds or by parting their roots, but most of them are annual. The Jerusalem artichoke belongs to this genus.

HELICOID PARABOLA, or the *parabolic spiral*, is a curve arising from the supposi-

tion that the common or Apollonian parabola is bent or twisted, till the axis come into the periphery of a circle, the ordinates still retaining their places and perpendicular positions with respect to the circle, all these lines still remaining in the same plane. Thus, the axis of a parabola being bent into the circumference BCDM (Plate Miscell. fig. 119.), and the ordinates CF, DG, &c. still perpendicular to it, then the parabola itself, passing through the extremities of the ordinates, is twisted into the curve BFG, &c. called the helicoid, or parabolic spiral.

Hence all the ordinates CF, DG, &c. tend to the centre of the circle, being perpendicular to the circumference.

Also, the equation of the curve remains the same as when it was a parabola; viz. putting $x =$ any circular absciss BC, and $y = CF$ the corresponding ordinate, then is $px = y^2$, where p is the parameter of the parabola.

HELICONIA, a genus of the monogynia order, in the pentandria class of plants. The spatha is universal and partial; there is no calyx; the corolla has three petals, and the nectarium two leaves; the capsule is three-grained. There are three species, beautiful herbaceous stove plants from South America and the West Indies.

HELICTERES, *the screw-tree*, a genus of the decandria order, in the gynandria class of plants, and in the natural method ranking under the 37th order, columniferæ. The calyx is monophyllous and oblique; there are five petals, and the nectarium consists of five petal-like leaflets; the capsules are intorted or twisted inwards. There are nine species, all natives of warm climates. They are shrubby plants, rising from five to fourteen feet in height, adorned with flowers of a yellow colour. They are propagated by seeds, but are tender, and in this country must be kept in a stove during the winter.

HELIOCARPUS, a genus of the digynia order, in the dodecandria class of plants, and in the natural method ranking under the 37th order, columniferæ. The calyx is tetraphyllous; the petals four; the styles simple; the capsule bilocular, compressed, and radiated lengthwise on each side. There is one species, a tree of La Vera Cruz.

HELIOCENTRIC *latitude of a planet*, the inclination of a line drawn between the centre of the sun and the centre of a planet, to the plane of the ecliptic, which may be thus determined.

If the circle FGH (Plate Miscell. fig. 121.) represent the orbit of the earth round the sun, and the inner one ANBn, be so placed as to incline to the plane of the other (on which account it appears in the form of an ellipsis), then when the planet is in the node n, it will appear in the ecliptic, and so have no latitude. But if it move to P, then, being seen from the sun, it will appear to decline from the ecliptic, or to have latitude; and the inclination of the line SP to the plane of the ecliptic, is called the planet's heliocentric latitude; the measure of which is the angle PS p, supposing the line Pp to be perpendicular to the plane of the ecliptic.

This heliocentric latitude will be continually increasing till the planet come to the point A, which they call the limit or utmost extent of it; and then it will decrease again till it reach the other node N, when it will

have no latitude; after which it will increase again, till it come to B, or its utmost latitude; and, lastly, decrease again, till the planet come to be in *n*, whence it set out.

HELIOCENTRIC place of a planet, in astronomy, the place of the ecliptic which in the planet would appear to a spectator placed at the centre of the sun.

The ingenious Dr. Halley gives the following method to find the heliocentric places of a planet, and its distances from the sun, which supposes only that the periodical time of the planet is known. Let KLB (fig. 120.) be the orbit of the earth, S the sun, P the planet, or rather the point in the plane of the ecliptic, in which the perpendicular let fall from the planet meets that plane. And first when the earth is in K, observe the geocentric longitude of the planet, and having the theory of the earth, we have the apparent longitude of the sun, and, consequently, the angle PKS. The planet, after it has completed an entire revolution, returns again to the point P, at which time suppose the earth in L; and there again, let the planet be observed, and find the angle PLS, the planet's elongation from the sun. Having the times of observations, we have the places of the earth in the ecliptic, or the points K and L; and, consequently, the angle LSK, and the sides LS and SK: wherefore we shall have the angles SKL and SLK, and the side LK. From the known angles SKP and SLP, take away the known angles SKL and SLK, and we shall have the angles PKL and PLK known; therefore in the triangle PLK, having all the three angles, and the side LK, we shall find the side PL; and in the triangle PLS, having the sides PL and LS, and the intercepted angle PLS, we shall have the angle LSP, which determines the heliocentric place, and its distance from the node according to the ecliptic, as also the side SP. But as the tangent of the geocentric latitude is to the tangent of the heliocentric, so is the curtate distance of the planet from the sun to its curtate distance from the earth. But as the geocentric latitude may be found by observation, the heliocentric latitude will also be found; by which, and the curtate distance of the planet from the sun, we can find the true distance.

HELIOCOMETES, a phenomenon sometimes observed about sun-setting; being a large luminous tail or column of light proceeding from the body of the sun, and dragging after it, not unlike the tail of a comet; whence the name.

HELIOPHILA, a genus of the siliquosa order, in the tetradynamia class of plants, and in the natural method ranking under the 39th order, siliquosæ. There are two nectaria recurved towards the vesicular base of the calyx. There are ten species, all herbaceous plants of the Cape.

HELIOSCOPE, in optics, a sort of telescope, peculiarly fitted for viewing the sun, without hurting the eyes. See OPTICS.

As the sun may be viewed through coloured glasses, without hurt to the eyes, if the object and eye-glasses of a telescope are made of coloured glass, as red or green, such a telescope will become an helioscope. But Mr. Huygens only used a plain glass, blacked at the flame of a candle on one side, and placed between the eye-glass and the eye, which answers the design of an helioscope very well.

VOL. I.

HELIOSTATA, in optics, an instrument invented by the late learned Dr. S. Gravesande, who gave it this name, from its fixing apparently the rays of the sun in an horizontal direction across the dark chamber, all the while it is in use.

HELIOTROPE, a precious stone of a green colour, streaked with red veins. Pliny says it is thus called, because, when cast into a vessel of water, the sun's rays falling on it seem to be of a blood-colour; and that, when out of the water, it gives a faint reflection of the figure of the sun, and is proper to observe eclipses of the sun as a helioscope. The heliotrope is also called oriental jasper, on account of its ruddy spots. It is found in the East Indies, as also in Ethiopia, Germany, &c. According to Dr. Thompson, the colour of this stone is different shades of green, often stained or striped with olive, yellow, and red. Found in mass, and in angular pieces. Specific gravity 2.6. Brittle, infusible before the blow-pipe.

HELIOTROPIUM, *turnsole*, a genus of the polygynia order, in the pentandria class of plants, and in the natural method ranking under the 41st order, asperifoliae. The corolla is salver-shaped and quinquefid, with lesser dents interjected alternately; the throat closed up by small arches formed in the corolla itself. There are 24 species, all of them natives of warm countries. Only one, called the tricocum, grows in Europe, and is a native of France, Spain, and Italy. It is only remarkable for the property of its berries. See COLOUR-MAKING.

HELIX, in geometry, the same with spiral. In architecture some authors make a difference between the helix and the spiral. A stair-case, according to Daviler, is an helix, or is helical, when the stairs or steps wind round a cylindrical newel; whereas the spiral winds round a cone, and is continually approaching nearer and nearer its axis.

HELIX, *the snail*, in zoology, a genus belonging to the order of vermes testacea. The shell consists of one spiral, brittle, and almost diaphanous valve; and the aperture is narrow. There are 60 species, principally distinguished by the figure of their shells. They are of various sizes, from that of a small apple to less than half a pea. Some of them live on land, frequenting woods and gardens, or inhabiting clefts of rocks and dry sand-banks. Others of them are aquatic, inhabiting ponds, deep rivers, and the ocean. The principal species are,

The *janthina*, with a violet-coloured shell, is remarkable for the extreme thinness of its texture, which breaks with the least pressure, and seems therefore entirely calculated to keep the open sea, or at least to shun rocky shores. It inhabits the seas of Europe, especially the Mediterranean, those of Asia and Africa, and also the ocean. The living animal, when touched, exudes a juice which stains the hands of a violet-colour. Dr. Hawkesworth, in his Account of Cook's Voyage, mistakes this shell for that which yielded the purpura of the ancients. But whoever looks into Pliny, can never have the least idea that the thin shell aforementioned could be the same with it. They had several shells which yielded the purple dye; but these were all rock-shells, and very different both in figure and hardness from the little

helix *janthina*, which is not calculated for the neighbourhood of rocks.

2. The *pomatia*, or exotic snail, with five spires, most remarkably ventricose, and fasciated with a lighter and deeper brown, is a native of France, where it inhabits the woods, but has been naturalized in England, where it inhabits the woods in the southern counties. It was introduced, it is said, by sir Kenelm Digby, whether for medical purposes, or as food, is uncertain: tradition says, that to cure his beloved wife of a decay was the object. They are quite confined to our southern counties. An attempt was made to bring them into Northamptonshire, but they would not live there. These are used as a food in several parts of Europe during Lent, and are preserved in an escargatoire, or a large place boarded in, with a floor covered half a foot deep with herbs, in which the snails nestle and fatten. They were also a favourite dish with the Romans, who had their cochlearia, a nursery similar to the above. Fulvius Hirpinus was the first inventor of this luxury, a little before the civil wars between Caesar and Pompey. The snails were fed with bran and sodden wine. If we could credit Varro, they grew so large, that the shells of some would hold ten quarts! People need not admire the temperance of the supper of the younger Pliny, which consisted of only a lettuce, three snails, two eggs, a barley-cake, sweet wine and snow, in case his snails bore any proportion in size to those of Hirpinus. Its name is derived not from any thing relating to an orchard, but from *opus*, an operculum, it having a very strong one. This seems to be the species described by Pliny, lib. viii. c. 39. which he says was scarce; that it covered itself with the opercle, and lodged under ground; and that they were at first found only about the maritime Alps, and more lately near Velitræ.

3. The *hortensis*, or garden-snail, is in form like the last, but less, and not umbilicated and clouded, or mottled with browns. It abounds with a viscid slimy juice, which it readily gives out by boiling in milk or water, so as to render them thick and glutinous. The decoctions in milk are apparently very nutritious and demulcent, and have been recommended in a thin acrimonious state of the humours, in consumptive cases and emaciations.

The eyes of snails are lodged in their horns, one at the end of each horn, which they can retract at pleasure. The manner of examining these eyes, which are four in number, is this: When the horns are out, cut off nimbly the extremity of one of them; and placing it before the microscope, you may discover the black spot at the end to be really a semiglobular eye. The dissection of this animal is very curious; for by this means the microscope not only discovers the heart beating just against the round hole near the neck, which seems the place of respiration, but also the liver, spleen, stomach, and intestines, with the veins, arteries, mouth and teeth, are plainly observable. The intestines of this creature are green, from its eating herbs, and are branched all over with fine capillary white veins; the mouth is like a hare's or rabbit's, with four or six needle-teeth, resembling those of leeches, and of a substance like horn. Snails are all hermaphrodites, having both sexes united in each individual. They

lay their eggs with great care in the earth, and the young ones are hatched with shells completely formed. Cutting off a snail's head, a little stone appears, which is supposed to be a great diuretic, and good in all nephritic disorders. Immediately under this stone the heart is seen beating; and the auricles are evidently distinguishable, and are membranous, and of a white colour; as are also the vessels which proceed from them.

Snails discharge their excrements at a hole in their neck; they also breathe by this hole, and their parts of generation are situated very near it.

So small an animal as the snail is not free from the plague of supporting other smaller animals on its body; and as in other animals we find these secondary ones either living on their surface, as lice, &c. or only in the intestines, as worms, it is very remarkable that the snail is infested in both these manners, lice being found sometimes on the surface of its body, and worms sometimes within its intestines. There is a part of the common garden snail, and of other of the like kinds, commonly called the collar. This surrounds the neck of the snail, and is considerably thick, and is the only part that is visible when the animal is retired quietly into its shell. In this state of the animal these insects which infest it are usually seen in considerable numbers marching about very nimbly on this part; besides, the snail, every time it has occasion to open its anus, gives them a place by which to enter into its intestines, and they often seize the opportunity.

Snails are great destroyers of fruit in our gardens, especially the better sorts of wall-fruit. Lime and ashes sprinkled on the ground where they most resort will drive them away, and destroy the young brood of them. It is a common practice to pull off the fruit they have bitten; but this should never be done, for they will eat no other till they have wholly eaten up this if it is left for them. See Plate Nat. Hist. fig. 223.

HELIX. See ANATOMY.

HELLEBORUS, *hellebore*, a genus of the polygynia order, in the polyandria class of plants, and in the natural method ranking under the 26th order, multisiliquæ. There is no calyx; but five or more petals; the nectaria are bilabiated and tubular; the capsules polyspermous, and a little erect. There are seven species, the most remarkable of which is the niger, commonly called Christmas-rose. It has roots composed of many thick fleshy spreading fibres, crowned by a large cluster of lobed leaves, consisting each of seven or eight obtuse fleshy lobes, united to one foot-stalk; and between the leaves several thick fleshy flower-stalks, three or four inches high, surmounted by large beautiful white flowers, of five roundish petals, and numerous filaments, appearing in winter, about or soon after Christmas.

This plant may be propagated either by seeds or parting the roots. It prospers in the open borders, or may be planted in pots to move when in bloom, in order to adorn any particular place; but it always flowers fairest and most abundantly in the front of a warm sunny border. The plants may be removed, and the roots divided for propagation, in September, October, or November; but the sooner in autumn it is done, the

stronger will the plants flower at their proper season.

The root of this plant was antiently used as a cathartic. The taste of it is acrid and bitter. Its acrimony, as Dr. Grew observes, is first felt on the tip of the tongue, and then spreads itself immediately to the middle, without being much perceived in the intermediate part. On chewing the root for a few minutes, the tongue seems benumbed, and affected with a kind of paralytic stupor, as when burnt by eating any thing too hot. The fibres are more acrimonious than the head of the root whence they issue. Black hellebore root, taken from 15 to 30 grains, proves a strong cathartic, and as such has been celebrated for the cure of maniacal disorders, and such also as were attributed to what the antients called the atra bilis. In mania, however, this root appears by no means to be possessed of any specific power. It does not indeed appear that our black hellebore acts with so much violence as that of the antients, whence many have supposed it to be a different plant; and indeed the descriptions which the antients have left us of their hellebore, do not agree with those of any of the sorts usually taken notice of by modern botanists. Another species has been discovered in the eastern countries, which Tournefort distinguishes by the name of *helleborus niger orientalis*, *amplissimo folio*, *caule præalto*, *flore purpurascens*, and supposes to be the true antient hellebore, from its growing in plenty about Mount Olympus, and in the island of Anticyra, celebrated of old for the production of this antimaniacal drug: he relates, that a scruple of this sort given for a dose, occasioned convulsions. Our hellebore is looked upon principally as an alterative; and is sometimes employed in small doses for promoting the uterine and urinary discharges, &c. It proves a powerful emmenagogue in plethoric habits, where steel is ineffectual or improper. In some parts of Germany a species of black hellebore has been made use of, which frequently produced violent, and sometimes deleterious, effects. It appears to be the fetid kind of Linnaeus, called in English settelwort, setterwort, or bastard hellebore. The roots of this may be distinguished from those of the true kind, by their being less black.

2. The hyemalis, with a beautiful yellow flower, which is the common harbinger of spring.

HELM of a ship, is a piece of timber fastened into the rudder, which comes forward into the steerage, or place where the person at the helm steers the ship, by holding the whipstaff in his hand, which is joined to the helm. They begin, however, to be left off, steering-wheels being used in their room.

There are several terms in the sea language relating to the helm: as, bear up the helm; that is, let the ship go more large before the wind: helm a mid-ship or right the helm; that is, keep it even with the middle of the ship: port the helm, put it over to the left side of the ship: starboard the helm, put it on the right side of the ship. See SHIP-BUILDING.

HELMET, an antient defensive armour worn by horsemen both in war and in tournaments. It covered both the head and face, only leaving an aperture in the front secured by bars, which was called the visor.

It is still used in heraldry by way of crest over the shield or coat of arms, in order to express the different degrees of nobility by the different manner in which it is borne. Thus a helmet in profile is given to gentlemen and esquires: to a knight, the helmet standing forward and the beaver a little open; the helmet in profile and open, with bars, belongs to all noblemen under the degree of a duke; and the helmet forward and open, with many bars, is assigned to kings, princes, and dukes. There is generally but one helmet upon a shield; but sometimes there are two, and even three: if there are two, they ought to face each other; and if three, the middlemost should stand directly forward, and the other two on the sides facing towards it.

HELMINTHOLITHUS, in natural history, a name given by Linnaeus to petrified bodies resembling worms. Of these he reckons four genera. 1. Petrified lithophyta, found in the mountains of Sweden. 2. Petrified shells. 3. Petrified zoophytes. 4. Petrified reptiles. See LITHOPHYTA, &c.

HELONIAS, a genus of the trigynia order, in the hexandria class of plants, and in the natural method ranking under the 10th order, coronariæ. The corolla is hexapetalous; there is no calyx; and the capsule is trilocular. There are two species, herbs of America.

HELVELIA, a genus of the class and order cryptogamia fungi. There are two species, natives of this country.

HELVINE. See POLYGONUM.

HEMATOPUS, in ornithology, a genus of the grallæ order. The generic character is: the bill compressed, the lip an equal wedge; nostrils linear; tongue a third part as long as the bill; feet formed for running, three-toed, cleft.

The *H. ostrolegus*, or oyster-catcher, inhabits almost every sea-shore, is sixteen and a half inches long, feeds on marine worms and insects, but chiefly on oysters and limpets, which it extracts from the shell with great dexterity. Eggs, four to five; colour, olive-yellow, with irregular purplish spots. This is the only species. See Plate Nat. Hist. fig. 219.

HEMEROBIOUS, in zoology, a genus of insects of the neuroptera order, the characters of which are these: the mouth is furnished with two teeth; the palpi are four; the wings are deflected but not plaited; and the antennæ are bristly and longer than the breast. There are 15 species, principally distinguished by their colours. This insect takes the name of hemerobius from the shortness of its life, which, however, continues several days. In the state of larva it is a great devourer of plant-lice, for which it has had bestowed upon it the appellation of lion of the plant-lice. The hemerobii, even after their transformation, preserve their carnivorous inclination. Not satisfied with making war upon the plant-lice, who tamely let themselves be devoured, they do not spare each other. The eggs of this insect are borne upon small pedicles, which are nothing but a gum spun out by the hemerobius by raising up the hinder part of its abdomen, and by that means the egg remains fastened to the upper part of the thread. Those eggs are deposited upon leaves, and set in the form of bunches. They have been taken for parasitic plants,

The larva, when hatched, finds there its food in the midst of plant-lice. In 15 or 16 days it has attained to its full growth. With its spinning-wheel at its tail, it makes itself a small, round, white, silky cod, of a close texture. In summer, at the end of three weeks, the hemerobius issues forth with its wings; but when the cod has not been spun till autumn, the chrysalis remains in it, the whole winter, and does not undergo its final metamorphosis till the ensuing spring. The flight of this insect is heavy: some species have an excrementitious smell. One goes by the name of the water-hemerobius, because it lives mostly at the water-side. See Plate Nat. Hist. fig. 224.

HEMEROCALLIS, *day-lily*, or *lily-asphodel*, a genus of the monogynia order, in the hexandria class of plants, and in the natural method ranking under the 10th order, coronariae. The corolla is campanulated, with the tube cylindrical; the stamina declining downward. There are five species, of which two are common here, viz.

1. The flava, or yellow day-lily, with strong fibrous roots, sending up large hollow keel-shaped leaves, two feet long, upright, leafless firm stalks, two feet high, dividing at top into several foot-stalks, each terminated by one large liliaceous yellow flower, of an agreeable odour. Of this there is a variety called the hemerocallis minor, or small yellow day-lily.

2. The fulva, reddish, or copper-coloured day-lily, has roots composed of strong fleshy fibres, and large oblong tubes; radical, keel-shaped, hollow, pointed leaves, a yard long, reflected at top, with leafless stalks, three or four feet high, and large copper-coloured liliaceous flowers. These have large stamina, charged with a kind of brown-coloured farina, which, on being touched or smelled to, is discharged in great plenty all over the hands and face. Both these species are hardy, and will thrive any where. They may be easily propagated by parting their roots in autumn, or almost any time after flowering, or before they begin to flower.

3. The japonica is a greenhouse plant, producing beautiful white flowers.

HEMERODROMI, in Grecian antiquity, centinels and guards appointed for the security and preservation of cities and other places. They went out of the city every morning as soon as the gates were opened, and kept patrolling all day about the place: sometimes also making excursions further into the country, to see that there were no enemies lying in wait to surprise them.

HEMERODROMI were also a sort of couriers among the antients, who only travelled one day, and then delivered their packets or dispatches to a fresh man, who run his day, and so on to the end of the journey.

HEMICYCLE. See ARCHITECTURE.

HEMIMERIS, a genus of the angiosperma order, in the didynamia class of plants. The capsule is bilocular, with one of the cells more gibbous than the other; the corolla is wheel-shaped, with one division greater, and inverse heart-shaped; the interstice of the divisions nectar-bearing. There are three species, herbaceous plants of the Cape.

HEMINA, in Roman antiquity, a liquid measure which, according to Arbuthnot, was equal to half a wine-pint English measure; its contents being 2.818 solid inches.

HEMIONITIS, a genus of the natural order of filices, belonging to the cryptogamia class of plants. The fructifications are in lines, decussating or crossing each other. There are eight species, natives of the West Indies.

HEMIPLEGIA. See MEDICINE.

HEMIPTERA, derived from *ἡμιπτερος* half-wing, in the Linnæan system, the second order of insects, comprehending twelve genera, viz. the blatta, mantis, gryllus, fulgora, cicada, notonecta, nepa, cimex, aphid, chermes, coccus, and thrips, and a great number of species.

HEMISPHERE, in geometry, the half of a globe or sphere, when it is supposed to be cut through its centre in the plane of one of its great circles. Thus the equator divides the terrestrial globe into the northern and southern hemisphere: in the same manner the meridian divides the globe into the eastern and western hemisphere; and the horizon into two hemispheres, distinguished by the epithets upper and lower. The centre of gravity of an hemisphere is five-eighths of the radius distant from the vertex.

HEMISPHERE is also used to denote a projection of half the terrestrial globe, or half the celestial sphere, on a plane, and frequently called planisphere.

HEMISTICH, in poetry, denotes half a verse, or a verse not completed. Of this there are frequent examples in Virgil's *Æneid*; but whether they were left unfinished by design or not, is disputed among the learned: such are *Ferro accincta vocat*, *Æn. II. v. 614*. And, *Italiam non sponte sequor*, *Æn. IV. v. 361*.

In reading common English verses, a short pause is required at the end of each hemistich, or half verse.

HEMLOCK. See CICUTA.

HEMP and **FLAX**. No hemp or flax is to be watered in any river, running water, stream, brook, or pond, where beasts are used to be watered, but only in their several ponds for that purpose, on pain of 20s. 33 Hen. VIII. c. 17.

Any persons may, in any place, corporate town, privileged or unprivileged, set up manufactories of hemp or flax; and persons coming from abroad, using the trade of hemp or flax-dressing, and of making thread, weaving cloth made of hemp or flax, or making tapestry hangings, twine or nets for fishery, cordage, &c. after three years, shall have the privileges of natural-born subjects. 15 Car. II. c. 15.

HEN. See PHASIANUS.

HENDECAGON, in geometry, a figure that has eleven sides, and as many angles. In fortification, hendecagon denotes a place defended by eleven bastions.

HENOTICON, in church history, a decree or edict of the emperor Zeno, made at Constantinople, in the year 482, by which he pretended to reconcile all parties under one faith.

HEPAR, a name formerly given to the combination of sulphur and alkali. It is now called sulphuret of potass.

HEPATIC GAS, the old name for the gas separated from sulphuret of alkali. It is now called sulphurated hydrogen gas.

HEPATICA. See ANEMONE.

HEPATITIS. See MEDICINE.

HEPTAGON, in geometry, a figure of seven sides and seven angles. When those sides and angles are all equal, the heptagon is said to be regular, otherwise it is irregular.

In a regular heptagon, the angle C, Plate Miscel. fig. 122, at the centre is $= 51^{\circ} \frac{1}{7}$, the angle DAB of the polygon is $= 128^{\circ} \frac{4}{7}$, and its half CAB $= 64^{\circ} \frac{2}{7}$. Also the area is $=$ the square of the side $AB^2 \times 3.6339124$, or $= AB^2 \times \frac{7}{4} t$, where t is the tangent of the angle CAB of $64^{\circ} \frac{2}{7}$ to the radius 1; or t is the root of the equation; $t^{12} - 26t^{10} + 143t^8 - 245t^6 + 143t^4 - 26t^2 + 1 = 0$; or $t = \sqrt{\frac{1+x}{1-x}} = \frac{1+\sqrt{1-y^2}}{y} =$

$\frac{y}{1-\sqrt{1-y^2}}$, where the value of x and y are the roots of the equations

$$x^6 - \frac{5}{4}x^4 + \frac{3}{8}x^2 - \frac{1}{16} = 0,$$

$$y^6 = \frac{7}{4}y^4 + \frac{7}{8}y^2 - \frac{7}{64} = 0.$$

HEPTAGON, in Fortification, a place fortified or strengthened with seven bastions for its defence.

HEPTAGONAL NUMBERS, are a kind of polygonal numbers in which the difference of the terms of the corresponding arithmetical progression is 5. Thus,

Arithmeticals, 1, 6, 11, 16, 21, 26, &c.

Heptagonals, 1, 7, 18, 34, 55, 81, &c.

where the heptagonals are formed by adding continually the terms of the arithmeticals, above them, whose common difference is 5.

One property, among many others, of these heptagonal numbers is, that if any one of them be multiplied by 40, and to the product add 9, the sum will be a square number.

$$\text{Thus } 1 \times 40 + 9 = 49 = 7^2;$$

$$\text{and } 7 \times 40 + 9 = 289 = 17^2;$$

$$\text{and } 18 \times 40 + 9 = 729 = 27^2;$$

$$\text{and } 34 \times 40 + 9 = 1369 = 37^2; \text{ \&c.}$$

Where it is remarkable that the series of squares so formed is $7^2, 17^2, 27^2, 37^2$, &c, the common difference of whose roots is 10, the double of the common difference of the arithmetical series from which the heptagonals are formed. See POLYGONALS.

HEPTAMERIS, in music, the seventh part of a meris, being, according to M. Sauveur, the forty-third part of the octave.

HEPTANDRIA, from *ἑπτά*, septem, and *ἀνδρ*, a man, the seventh class in Linnæus's sexual method, consisting of plants with hermaphrodite flowers, which have seven stamina or male organs. The orders are four, derived from the number of styles or female organs. See BOTANY.

HEPTANGULAR FIGURE, in geometry, is one that has seven angles, and therefore also seven sides.

HERACLEUM, a genus of the pentandria digynia class of plants, the general flower of which is difform and radiated; the single flowers of the disc consist each of five equal petals, but those of the radius consist of five unequal petals. The fruit is elliptic, compressed, and striated on each side in the middle, and contains two oval compressed seeds. To this genus belongs the sphondylium or cow's parsnep of authors. There are six species.

HERACLIDÆ, or *return of the HERACLIDÆ into Peloponnesus*, in chronology, a famous epocha, that constitutes the beginning of prophane history; all the time preceding that period being accounted fabulous. This return happened in the year of the world 2862, an hundred years after they

were expelled, and eighty after the destruction of Troy.

HERALD, is an officer at arms, whose business is to denounce war, proclaim peace, or be otherwise employed by the king in martial messages or other business.

Heralds are the judges and examiners of gentlemen's coats of arms, and preservers of genealogies; and they marshal all solemnities at the coronation of princes, and funerals of great persons.

HERALDRY, the science which teaches how to blazon, or explain in proper terms, all that belongs to coats of arms; and how to marshal, or dispose regularly, divers arms on a field.

Arms, or coats of arms, are hereditary marks of honour, made up of fixed and determined colours and figures, granted by sovereign princes, as a reward for military valour, or some signal public service performed. These are intended to denote the descent and alliance of the bearer, or to distinguish states, cities, societies, &c. civil, ecclesiastical, and military.

Men in all ages have made use of figures of living creatures, or symbolical signs, to denote the bravery and courage either of their chief or nation, to render themselves the more terrible to their enemies, and even to distinguish themselves or families, as names do individuals. Thus the Egyptians bore an ox, the Athenians an owl, the Goths a bear, the Romans an eagle, the Franks a lion, and the Saxons a horse: the last is still borne in the arms of his present Britannic majesty. As to hereditary arms of families, William Camden, sir Henry Spelman, and other judicious heralds, agree, that they began no sooner than towards the latter end of the 11th century.

With tournaments first came up coats of arms; which were a sort of livery, made up of several lists, fillets, or narrow pieces of stuff of many colours, from whence came the fess, the bend, the pale, &c. which were the original charges of family-arms: for they who never had been at tournaments had not such marks of distinction. They who enlisted themselves in the croisades took up also several new figures hitherto unknown in armorial ensigns; such as alerions, bezants, escallop-shells, martlets, &c. but more particularly crosses, of different colours for distinction's sake. From this it may be concluded, that heraldry, like most human inventions, was insensibly introduced and established; and that, after having been rude and unsettled for many ages, it was at last methodized, perfected, and fixed, by the croisades and tournaments.

These marks of honour are called arms, from their being principally and first worn by military men at war and tournaments, who had them engraved, embossed, or depicted on shields, targets, banners, or other martial instruments. They are also called coats of arms, from the custom of the antients embroidering them on the coats they wore over their arms, as heralds do to this day.

Arms are distinguished by different names, to denote the causes of their bearing; such as arms of dominion; of pretension; of concession; of community; of patronage; of family; of alliance; of succession.

Arms of dominion, or sovereignty, are

those which emperors, kings, and sovereign states do constantly bear; being annexed to the territories, kingdoms, and provinces, they possess. Thus the three lions are the arms of England, the harp those of Ireland, &c.

Arms of pretension are those of such kingdoms, provinces, or territories, to which a prince or lord has some claim, and which he adds to his own, although the said kingdoms or territories may be possessed by a foreign prince or lord. Thus the kings of England have quartered the arms of France with their own ever since Edward III. laid claim to the kingdom of France, which happened in the year 1330, on account of his being son to Isabella, sister to Charles the Handsome, who died without issue.

Arms of concession, or augmentation of honour, are either entire arms, or else one or more figures, given by princes as a reward for some extraordinary service. We read in history that Robert Bruce, king of Scotland, allowed the earl of Winton's ancestor to bear, in his coat-armour, a crown supported by a sword, to shew that he, and the clan Seaton, of which he was the head, supported his tottering crown.

Arms of community are those of bishoprics, cities, universities, academies, societies, companies, and other bodies corporate.

Arms of patronage are such as governors of provinces, lords of manors, patrons of benefices, &c. add to their family-arms, as a token of their superiority, rights, and jurisdiction. These arms have introduced into heraldry, castles, gates, wheels, ploughs, rakes, harrows, &c.

Arms of family, or paternal arms, are those that belong to one particular family, that distinguish it from others, and which no person is suffered to assume without committing a crime, which sovereigns have a right to restrain and punish.

Arms of alliance are those which families or private persons take up and join to their own, to denote the alliances they have contracted by marriage. This sort of arms is either impaled, or borne in an escutcheon of pretence, by those who have married heirs.

Arms of succession are such as are taken up by them who inherit certain estates, manors, &c. either by will, entail, or donation, and which they either impale, or quarter with their own arms; which multiplies the titles of some families out of necessity, and not through ostentation, as many imagine.

These are the eight classes under which the different sorts of arms are generally ranged; but there is a sort which blazoners call assumptive arms, being such as are taken by the caprice or fancy of upstarts, though of ever so mean extraction, who, being advanced to a degree of fortune, assume them without a legal title.

The essential and integral parts of arms are these: 1. The escutcheon. 2. The tinctures. 3. The charges. 4. The ornaments.

Of the shield or escutcheon.—The shield or escutcheon is the field or ground whereon are represented the figures that make up a coat of arms: for these marks of distinction were put on bucklers or shields before they were placed on banners, standards, flags, and

coat-armour; and wherever they may be fixed, they are still on a plane or superficies whose form resembles a shield.

Shields, in heraldry called escutcheons or scutcheons, from the Latin word *scutum*, have been, and still are, of different forms, according to different times and nations. Amongst antient shields, some were almost like a horseshoe, such as is represented by a few of the figures of escutcheons; others triangular, somewhat flat or rounded at the bottom. The English, French, Germans, and other nations, have their escutcheons formed different ways, according to the carver's or painter's fancy: of these various examples are contained in the plates of heraldry. But the shield of maids, widows, and of such as are born ladies, and are married to private gentlemen, is of the form of a lozenge (See Plate II).

Armorists distinguish several parts or points in escutcheons, in order to determine exactly the position of the bearings they are charged with; they are here denoted by the first nine letters of the alphabet, ranged in the following manner (See Plate I).

The knowledge of these points is of great importance, and ought to be well observed, for they are frequently occupied with several things of different kinds. It is necessary to observe, that the dexter side of the escutcheon is opposite to the left hand, and the sinister side to the right hand of the person that looks on it.

Distinctions of houses. These distinctions inform us how the bearer of each is descended from the same family; they also denote the subordinate degrees in each house from the original ancestors, viz.

First house. For the heir or first son the label; second son the crescent; third son the mullet; fourth son the martlet; fifth son the annulet; sixth son the fleur-de-lis.

Second house. The crescent, with the label on it, for the first son of the second son. The crescent on the crescent for the second son of the second son of the first house, &c. See the Plate.

By the *tinctures* or colours is meant that variety of hue of arms common both to shields and their charges: the colours generally used, are red, blue, sable, vert, purple. Note, yellow and white, termed or and argent, are metals; these colours are represented in engravings by dots and lines, as in the Plate.

Or is expressed by dots.

Argent is plain.

Gules, by perpendicular lines.

Azure, by horizontal lines.

Sable, by perpendicular and horizontal lines crossing each other.

Vert, by diagonal lines from the dexter chief to the sinister base point.

Purple, by diagonal lines from the sinister chief to the dexter base point.

Furs.—There are different kinds, and represent the hairy skins of certain animals, prepared for the linings of robes of state; and antiently shields were covered with furred skins: they are used in coats of arms, viz.

Ermine, is black spots on a white field.

Ermines, is a field black with white spots.

Erminois, is a field gold with black spots.

Vair, is white and blue, represented by figures of small escutcheons arranged in a

line, so that the base argent is opposite to the base azure.

Potent-counter-potent, is a field covered with figures like crutch heads. See Plate.

Charges, are whatsoever bearings or figures are borne in the field of a coat of arms.

Rampant, signifies the lion standing erect on one of the hind legs.

Rampant-gardant, is a lion standing on his hind leg, looking full-faced.

Rampant-regardant, standing upon his hinder leg, looking back towards his tail.

Passant: this term is to express the lion in a walking position.

Sejant, for the lion sitting, as the example.

Saliant, is when the lion is leaping or springing forward, as the example.

Couchant, is a lion lying at rest, with the head erect.

Passant-gardant, for a beast, when walking, with its head looking full-faced.

Couped, cut off smooth and even, as the example.

Erased, signifying torn or plucked off, as the example.

Demy, is the half of any charge, as the example, a demy lion.

Dormant, for sleeping with its head resting on its fore paws.

Partition lines, by which is understood a shield divided or cut through by a line or lines, either horizontal, perpendicular, diagonal, or transverse: the engraved examples are the crooked lines of partition, viz. engrailed, invecked, wavy, nebule, imbattled, raguly indented, dancette, dove-tail. See Plate I.

Roundels are round figures, much used in arms: the English heralds vary their names according to their colour, thus:

| | | |
|---------|-----------------|----------|
| Or, | } is termed a { | Bezant. |
| Argent, | | Plate. |
| Gules, | | Tortaux. |
| Azure, | | Hurt. |
| Sable, | | Pellet. |
| Vert, | | Pomey. |
| Purple, | | Golpe. |

Crescent, or half-moon, having its horns turned upwards.

Increscent, differs from the crescent, by having its horns turned to the dexter side.

Decrescent, is the reverse of the increscent, having its horns turned to the sinister side.

Rose, is represented, in heraldry, full-blown, with fine green barbs, and seeded in the middle.

Annulet, or ring, and by some authors supposed to be rings of mail.

Chess-rook. This piece is used in the game of chess.

Star, in heraldry, is termed an estoile, having six waved points.

Trefoil, or three-leaved grass.

Quatrefoil, or four-leaved grass.

Cinquefoil, or five-leaved grass.

Masle, is in shape like the lozenge, but is always perforated, as the example.

Fountain, an heraldic term for a roundle barry wavy of six argents and azure.

Billet, a small parallelogram, supposed to be letters made up in the form of the example.

Rustre, is a lozenge pierced round in the middle.

Gutte, in heraldry, signifies drops of any thing liquid, and, according to their colour, are termed as follow: if

| | |
|---------|------------------|
| Or, | Gutte d'or. |
| Argent, | Gutte d'eau. |
| Vert, | Gutte de olive. |
| Gules, | Gutte de sang. |
| Azure, | Gutte de larmes. |
| Sable, | Gutte poix. |

Fess, an ordinary composed of two horizontal lines drawn across the centre of the shield.

Chevron, an ordinary, in form like two rafters of a house, or a pair of compasses extended.

Bend, an ordinary, drawn diagonally from the dexter chief to the sinister base, and takes up one-third of the field.

Pale, an ordinary, which is placed perpendicular in the centre of the shield.

Chief, an ordinary, which always occupies the upper part of the shield, and contains in depth the third of the field.

Cross, an ordinary, composed of four lines, four perpendicular, and two transverse.

Saltire, an ordinary, in form like the cross of St. Andrew.

Bend-sinister, which is placed diagonally from the sinister chief to the dexter base of the shield.

Quarter, an ordinary, formed of two lines, one perpendicular, the other horizontal, taking up one-fourth of the field, as the example.

Canton, an ordinary, in form like the quarter, but the size is only the third part of the chief.

Pile, an ordinary, like the foot of the pile that is driven into the ground to make the foundation of a building in swampy ground.

Flanches, are composed of two circular lines, and are always borne double, as the example.

Flory, a cross, the ends terminating in fleurs-de-lis.

Moline, a cross, which turns round both ways at the extremities, like a hook.

Pattee, a cross, small in the centre, and widening to the ends, which are very broad.

Croslet, a cross, crossed again at the extremities at a small distance from each of the ends.

Lozenge, a four-cornered figure, like a pane of glass in old casements, supposed to be a physical composition given for colds, and was invented to distinguish eminent physicians.

Mullet, consists of five points, and pierced in the centre, and is supposed to represent a spur rowel.

Mill-rind, a cross, in form like the mill-rind which carries the millstone, and is perforated in the centre.

Water-boujet, antiently used as a vessel by soldiers for carrying water in long marches.

Helmets, were formerly worn as a defensive weapon to cover the bearer's head: a helmet is now placed over a coat of arms as its chief ornament, and a mark of gentility. The

First is a side-faced helmet of steel, with the vizor shut, for an esquire.

Second is a full-faced helmet of steel, with the vizor open, for knights or baronets.

Third is a side-faced helmet of steel, the bars and ornaments gold, for the nobility.

Fourth is a full-faced helmet, with bars all gold, for the sovereign and princes of the blood royal.

Close, signifies the wings of a bird are down, and close to the body.

Rising. This term is for a bird when in a position as if preparing to fly.

Displayed, signifies the wings of an eagle to be expanded, as the example.

Volant, a term for any bird represented flying.

Tripping, a term for a stag, antelope, or hind, when walking.

Courant, for a stag, or horse, or greyhound, running.

At gaze, is a term for a stag or hind; when looking full-faced, is termed at gaze.

Lodged, signifies the stag to be at rest on the ground.

Inverted, is for two wings conjoined, and the points of the wings downwards.

Erect, is for two wings conjoined, and the points erect, or upwards.

Hauriant. This term is for a fish when erect, paleways, as putting its head above water.

Naïant, for a fish, when borne horizontally across the shield, as swimming.

Cockatrice, a chimerical figure used in heraldry; its beak, wings, legs, comb, wattles, and spurs, partake of the fowl; and its body and tail of the snake.

Wyvern. This, like the former, is chimerical, and differs from the cockatrice in its head, having no comb, wattles, or spurs.

Dragon. This is an heraldic figure, as drawn by heralds. See the example.

Tiger. This, like the former, is of heraldic creation; being so different from the tiger of nature, it is termed the heraldic tiger.

Checky, is a shield or bearing, covered with small squares of different colours alternately.

Gyronny, is a shield divided into six or eight triangular parts of different colours, and the points all meeting in the centre of the shield.

Paly, is a shield divided into four, six, or more equal parts, by perpendicular lines, consisting of two colours.

Barry, is a shield divided into four, six, or more equal parts, by horizontal lines of two colours.

Bachelor.—The arms of a bachelor, whilst he remains such, he may quarter his paternal coat with other coats, if they belong to him, but he may not impale it till he is married.

Married man.—A married man is to conjoin the coat armours of himself and wife in one escutcheon paleways; the man's on the dexter side of the shield, and the woman's on the sinister side.

An heiress.—When an heiress is married, her arms are not to be impaled with her husband's, but are to be borne on an escutcheon of pretence, placed in the centre of the shield. Note, the escutcheon of pretence displays his pretension to her estate; and if the husband has issue by her, the heir of those two inheritors shall bear the hereditary coats of father and mother quarterly.

Quarterly.—Is an arms divided into four parts by a perpendicular and horizontal line crossing each other, in the centre of the shield, into four equal parts, termed quarters.

Maid.—The arms of a maid are to be placed in a lozenge; and if her father bore any difference in his coat the same is to be continued; for by the mark of cadency of her father's will be denoted what branch she is from.

Widow.—The arms of a widow are to be impaled with the arms of her late husband;

her husband on the dexter side, and her's on the sinister side, upon a lozenge, as the example.

Knight of the garter and his lady.—When a knight of the garter is married, his wife's arms must be placed in a distinct shield, because his arms are surrounded with the ensign of that order; for though the husband may give his equal share of the shield and hereditary honour, yet he cannot share his temporary order of knighthood with her.

Commoner and his lady.—The arms of a commoner married to a lady of quality: he is not to impale her arms with his own; they are to be set aside of one another in separate shields, as the lady still retains her title and rank. See the example.

Of the external ornaments of escutcheons.—The ornaments that accompany or surround escutcheons denote the birth, dignity, or office, of the person to whom the coat of arms appertaineth; and obtains both among the laity and clergy. The chief of which are as follow:

Crowns.—The first crowns were only diadems, bands, or fillets; afterwards they were composed of branches of divers trees, and then flowers were added to them. Among the Greeks, the crowns given to those who carried the prize at the Isthmian games, were of pine; at the Olympic, of laurel; and at the Nemean, of smallage. The Romans had various crowns to reward martial exploits and extraordinary services done to the republic. Examples of some of these crowns are frequently met with in modern achievements.

Modern crowns are only used as an ornament, which emperors, kings, and independent princes set on their heads, in great solemnities, to denote their sovereign authority. These are described in heraldry as follow:

The imperial crown is made of a circle of gold, adorned with precious stones and pearls, heightened with fleurs-de-lis, bordered and seeded with pearls, raised in the form of a cap voided at the top, like a crescent. From the middle of this cap rises an arched fillet enriched with pearls, and surmounted of a mound, whereon is a cross of pearls. See Plate II.

The crown of the kings of Great Britain is a circle of gold, bordered with ermine, enriched with pearls and precious stones, and heightened up with four crosses pattee, and four large fleurs-de-lis alternately; from these rise four arched diadems adorned with pearls, which close under a mound, surmounted of a cross like those at bottom.

The crowns of Spain and Portugal are a ducal coronet, heightened up with eight arched diadems that support a mound, ensigned with a plain cross. Those of Denmark and Sweden are both of the same form; and consist of eight arched diadems, rising from a marquis's coronet, which conjoin at the top under a mound ensigned with a cross botone. The crowns of most other kings in Europe are circles of gold, adorned with precious stones, and heightened up with large trefoils, and closed by four, six, or eight diadems, supporting a mound, surmounted of a cross.

The great Turk bears over his arms a turban, enriched with pearls and diamonds, under two coronets, the first of which is made of pyramidal points heightened up with large pearls, and the uppermost is surmounted with crescents.

The pope appropriates to himself a tiara or long cap of golden cloth, from which hang two pendants embroidered and fringed at the ends, semée of crosses of gold. This cap is inclosed by three marquis's coronets; and has on its top a mound of gold, whereon is a cross of the same, which cross is sometimes represented by engravers and painters pommetted, recrossed, flowery, or plain. It is a difficult matter to ascertain the time when these haughty prelates assumed the three forementioned coronets. See Plate II.

Coronets.—The coronet of the prince of Wales, or eldest son of the king of Great Britain, was antiently a circle of gold set round with four crosses-pattee, and as many fleurs-de-lis alternately; but since the Restoration it has been closed with one arch only, adorned with pearls, and surmounted of a mound and cross, and bordered with ermine like the king's. But besides the coronet his royal highness has another distinguishing mark of honour, peculiar to himself, viz. a plume of three ostrich feathers, with an antient coronet of a prince of Wales. Under it, in a scroll, is this motto, *Ich dien*, which in the German or old Saxon language signifies "I serve." This device was at first taken by Edward prince of Wales, commonly called the black prince, after the famous battle of Cressy, in 1346, where having with his own hand killed John, king of Bohemia, he took from his head such a plume, and put it on his own. See Plate I.

The coronet of all the immediate sons and brothers of the kings of Great Britain is a circle of gold, bordered with ermine, heightened up with four fleurs-de-lis, and as many crosses-patee alternate. The particular and distinguishing form of such coronets as are appropriated to princes of the blood royal, is described and settled in a grant of Charles II. the 13th of his reign. See Plate I.

The coronet of the princesses of Great Britain is a circle of gold, bordered with ermine, and heightened up with crosses-pattee, fleurs-de-lis, and strawberry leaves alternate; whereas a prince's coronet has only fleurs-de-lis and crosses.

A duke's coronet is a circle of gold bordered with ermine, enriched with precious stones and pearls, and set round with eight large strawberry or parsley leaves. See Plate I.

A marquis's coronet is a circle of gold, bordered with ermine, set round with four strawberry leaves, and as many pearls on pyramidal points of equal height, alternate. See Plate I.

An earl's coronet is a circle of gold, bordered with ermine, heightened up with eight pyramidal points or rays, on the tops of which are as many large pearls, that are placed alternately with as many strawberry leaves, but the pearls much higher than the leaves. See Plate I.

A viscount's coronet differs from the preceding ones as being only a circle of gold bordered with ermine, with large pearls set close together on the rim, without any limited number, which is his prerogative above the baron, who is limited. See Plate I.

A baron's coronet, which it appears was granted by king Charles II., is formed with six pearls set at equal distances on a gold circle, bordered with ermine, four of which only are seen on engravings, paintings, &c.

to shew he is inferior to the viscount. See Plate I.

The eldest sons of peers, above the degree of a baron, bear their father's arms and supporters with a label, and use the coronet appertaining to their father's second title; and all the younger sons bear their arms with proper differences, but use no coronets.

As the crown of the king of Great Britain is not quite like that of other potentates, so do most of the coronets of foreign noblemen differ a little from those of the British nobility.

Mitres.—The archbishops and bishops of England and Ireland place a mitre over their coat of arms. It is a round cap pointed and cleft at the top, from which hang two pendants fringed at both ends; with this difference, that the bishop's mitre is only surrounded with a fillet of gold, set with precious stones, whereas the archbishop's issues out of a ducal coronet. See Plate I.

This ornament, with other ecclesiastical garments, is still worn by all the archbishops and bishops of the church of Rome, whenever they officiate with solemnity; but it is never used in England otherwise than on coats of arms, as before mentioned.

The first archbishop's consecration in England was in the year 568. No mitre but an archbishop's is borne upon a ducal coronet, except the bishop of Durham, that see being a principality.

The first bishop's consecration in England was in the year 516.

Chapeaux, wreaths, and crests.—A chapeau is an antient hat, or rather cap, of dignity, worn by dukes, generally scarlet-coloured velvet on the outside, lined and turned up with fur; frequently to be met with above an helmet, instead of a wreath, under gentlemen's and noblemen's crests. Heretofore they were seldom to be found, as of right appertaining to primate families; but by the grants of Robert Cooke, Clarencieux, and other succeeding heralds, these, together with ducal coronets, are now frequently to be met with in families, who yet claim not above the degree of gentlemen. See Plate II.

The wreath is a kind of roll made of two skains of silk of different colours twisted together, which antient knights wore as a head-dress when equipped for tournaments. The colours of the silk are always taken from the principal metal and colour contained in the coat of arms of the bearer. They are still accounted as one of the lesser ornaments of escutcheons, and are placed between the helmet and the crest (see Plate II.). In the time of Henry I. and long after, no man who was under the degree of a knight had his crest set on a wreath; but this, like other prerogatives, has been infringed so far that every body now-a-days wears a wreath.

The crest is the highest part of the ornaments of a coat of arms. It is called crest, from the Latin word *crista*, which signifies comb or tuft, such as many birds have upon their heads, as the peacock, pheasant, &c. in allusion to the place on which it is fixed. See Plate II. crest of the prince of Wales.

Crests were formerly great marks of honour, because they were only worn by heroes of great valour, or by such as were advanced to some superior military command, in order that they might be the better distinguished in an engagement, and thereby rally their men

if dispersed; but they are at present considered as a mere ornament. The crest is frequently a part either of the supporters, or of the charge borne in the escutcheon. Thus the crest of the royal achievement of Great Britain is a "lion guardant crown'd." See Plate II. There are several instances of crests that are relative to alliances, employments, or names; and which on that account have been changed.

The scroll and supporters.—The scroll is the ornament usually placed below the crest, containing a motto, or short sentence, alluding thereto, or to the bearings, or to the bearer's name, as in the two following instances. The motto of the noble earl of Cholmondeley is, "Cassis tutissima virtus;" i. e. "Virtue is the safest helmet;" on account of the helmet in the coat of arms. The motto of the right hon. lord Fortescue is, "Forte scutum salus ducum;" i. e. "A strong shield is the safety of the commanders;" alluding to the name of that antient family. Sometimes it has reference to neither, but expresses something divine or heroic; as that of the earl of Scarborough, which is, "Murus areus conscientia sana;" i. e. "A good conscience is a wall of brass." Others are enigmatical; as that of the royal achievement, which is, "Dieu et mon droit;" i. e. "God and my right;" introduced by Edward III. in 1340, when he assumed the arms and title of king of France, and began to prosecute his claim, which occasioned long and bloody wars, fatal, by turns, to both kingdoms. Mottos, though hereditary in the families that first took them up, have been changed on some particular occasions, and others appropriated in their stead, instances of which are sometimes met with in the history of families.

Supporters are figures standing on a scroll, and placed at the side of the escutcheon; they are so called because they seem to support or hold up the shield. Supporters have formerly been taken from such animals or birds as are borne in the shields, and sometimes they have been chosen as bearing some allusion to the names of those whose arms they are made to support. The supporters of the arms of Great Britain, since king James the First's accession to the throne, are, a lion rampant guardant crowned or, on the dexter side, and an unicorn argent, crowned, armed, unguled, maned and gorged with an antique crown, to which a chain is affixed, all or, on the sinister. See Plate II.

It is to be observed, that bearing coats of arms supported, is, according to the heraldic rules of England, the prerogative, 1st, Of those called nobles majores, viz. dukes, marquises, earls, viscounts, and barons; 2d, Of all knights of the garter, though they should be under the degree of barons; 3d, Of knights of the Bath, who both receive on their creation a grant of supporters; and, lastly, of such knights as the king chooses to bestow this honour upon.

Of the laws of heraldry, and the method of marshalling coats of arms.—1. The first and most general rule is, to express heraldic distinctions in proper terms, so as not to omit any thing that ought to be specified, and at the same time to be clear and concise without tautology. 2. Begin with the tincture of the field, and then proceed to the principal charges which possess the most honour-

able place in the shield, such as fess, cheveron, &c. always naming that charge first which lies next and immediately upon the field. 3. After naming the tincture of the field, the honourable ordinaries, or other principal figures, you must specify their attributes, and afterwards their metal or colour. 4. When an honourable ordinary, or some one figure, is placed upon another, whether it be a fess, cheveron, cross, &c. it is always to be named after the ordinary or figure over which it is placed, with one of these expressions, surmount, or over all. 5. In the blazoning of such ordinaries as are plain, the bare mention of them is sufficient; but if an ordinary should be made of any of the crooked lines mentioned above, its form must be specified; that is, whether it be engrailed, wavy, &c. 6. When a principal figure possesses the centre of the field, its position is not to be expressed, or (which amounts to the same thing) when a bearing is named, without specifying the point where it is placed, then it is understood to possess the middle of the shield. 7. The number of the points of mullets or stars must be specified when more than five; and also if a mullet or any other charge be pierced, it must be mentioned as such, to distinguish it from what is plain. 8. When a ray of the sun, or other single figure, is borne in any other part of the escutcheon than the centre, the point it issues from must be named. 9. The natural colour of trees, plants, fruits, birds, &c. is no otherwise to be expressed in blazoning but by the word proper; but if discoloured, that is, if they differ from their natural colour, it must be particularized. 10. When three figures are in a field, and their position is not mentioned in the blazoning, they are always understood to be placed two above, and one below. 11. When there are many figures of the same species borne in a coat of arms, their number must be observed as they stand, and must be distinctly expressed.

By marshalling coats of arms is to be understood the art of disposing divers of them in one escutcheon, and of distributing their contingent ornaments in proper places. Various causes may occasion arms to be thus conjoined, which are comprised under two heads, viz. manifest and obscure. What is meant by manifest causes in the marshalling of coats of arms, are such as betoken marriages, or a sovereign's gift, granted either through the special favour of the prince, or for some eminent services. Concerning marriages it is to be observed,

1. When the coats of arms of a married couple, descended of distinct families, are to be put together in one escutcheon, the field of their respective arms is conjoined paleways, and blazoned parted per pale, baron and femme, two coats; first, &c. In which case the baron's arms are always to be placed on the dexter side, and the femme's arms on the sinister side.

2. If a widower marry again, his late and present wife's arms are "to be placed on the sinister side, in the escutcheon with his own, and parted per pale. The first wife's coat shall stand on the chief, and the second on the base; or he may set them both in pale with his own, the first wife's coat next to himself, and his second outermost. If he should marry a third wife, then the two first matches shall stand on the chief, and the

third shall have the whole base. And if he take a fourth wife, she must participate one-half of the base with the third wife, and so will they seem to be so many coats quartered." But it must be observed that these forms of impaling are meant of hereditary coats, whereby the husband stands in expectation of having the hereditary possessions of his wife united to his patrimony. Note. If a man marry a widow, he marshals her maiden arms only.

3. In the arms of femmes joined to the paternal coat of the baron, the proper differences by which they were borne by the fathers of such women must be inserted.

4. If a coat of arms that has a bordure be impaled with another, as by marriage, then the bordure must be wholly omitted in the side of the arms next the centre.

5. The person that marries an heiress, instead of impaling his arms with those of his wife, is to bear them in an escutcheon placed in the centre of his shield, which, on account of its showing forth his pretension to her estate, is called an escutcheon of pretence, and is blazoned surmount, that is, over-all. But the children are to bear the hereditary coat of arms of their father and mother quarterly, which denotes a fixed inheritance, and so transmit them to posterity. The first and fourth quarters generally contain the father's arms, and the second and third the mother's; except the heirs should derive not only their estate, but also their title and dignity, from their mother.

6. If a maiden or dowager lady of quality marry a commoner, or a nobleman inferior to her in rank, their coats of arms may be set beside one another, in two separate escutcheons, upon one mantle or drapery, and the lady's arms ornamented according to her title. See Plate II.

7. Archbishops and bishops impale their arms differently from the fore-mentioned coats, in giving the place of honour, that is, the dexter side, to the arms of their dignity, as it is expressed in Plate I. which represents the coat of arms of a supposed archbishop of Canterbury and bishop of an English see.

With respect to such armorial ensigns as the sovereign thinks fit to augment a coat of arms with, they may be marshalled in various ways, as may be seen in the arms of his grace the duke of Rutland, and many others.

So far the causes for marshalling divers arms in one shield, &c. are manifest. As to such as are called obscure, that is, when coats of arms are marshalled in such a manner that no probable reason can be given why they are so conjoined, the explanation of them must be left to the heralds.

Of the orders of knighthood, &c.—The baronet's mark of distinction, or the arms of the province of Ulster in Ireland, granted and made hereditary in the male line by king James I. who erected this dignity on the 22d of May, 1611, in the 9th year of his reign, in order to propagate a plantation in the fore-mentioned province. This mark is argent, a sinister hand couped at the wrist, and erected gules; which may be borne either in a canton, or in an escutcheon, as will best suit the figures of the arms. The antient and respectable badge of the most noble order of the garter, was instituted by king Edward III. 1349, in the 27th year of his reign. This honourable augmentation is

a deep blue garter, surrounding the arms of such knights, and inscribed with his motto, "Honi soit qui mal y pense." See Plate II.

The arms of those who are knights of the orders of the Bath, of the Thistle, or of St. Patrick, are marshalled in the same manner, with this difference only, that the colour and motto accord with the order to which it belongs. Thus the motto, "Quis separabit 1783," on the light blue ribbon of the order, surrounds the escutcheon of a knight of St. Patrick. "Nemo me impune lacessit," on a green ribband, distinguishes a knight of the Thistle; and "Tria juncta in uno," on red, a knight of the Bath. It is to be observed that none of the orders of knighthood are hereditary. The honours of a baronet of Ulster, and of a baronet of Nova Scotia (created by patent in 1602), descend to the heirs male.

With regard to the emblazoning of the wife's arms in the case of the husband being noble; or where, on the other hand, the wife is noble in her own right, and the husband a commoner, these will be found exemplified in Plate II.

For representations of the badges of the several orders of knighthood, see Plate II. See ARMS, BLAZONING, PRECEDENCY, and the several terms of heraldry in alphabetical order.

HERBAL, is sometimes used for what is more usually called hortus siccus. See HORTUS SICCUS.

HERCULES, in astronomy, a constellation of the northern hemisphere, said to contain from 28 to 95 stars.

HEREDITAMENTS, all such things immoveable, whether corporeal or incorporeal, as a man may leave to his heirs, by way of inheritance; or not being otherwise devised, do naturally descend to him who is next heir of blood, and fall not within the compass of an executor or administrator, as chattels do. It is a word of large extent, and much used in conveyances; for by the grant of hereditaments, isles, seignories, manors, houses, and lands of all sorts, charters, rents, services, advowsons, commons, and whatever may be inherited, will pass. Co. Lit. 6.

Hereditaments are of two kinds, corporeal and incorporeal. Corporeal hereditaments consist wholly of substantial and permanent objects, all which may be comprehended under the general denomination of land only: for land comprehends in its legal signification any ground, soil, or earth whatsoever, as arable, meadows, pastures, woods, moors, waters, marshes, furzes, and heath. 1 Inst. 4.

Incorporeal hereditaments are not the object of sensation, neither can they be seen or handled, are creatures of the mind, and exist only in contemplation: they are principally of ten sorts, viz. advowsons, tithes, commons, ways, offices, dignities, franchises, corollies or presents, and rents. Black.

HERESY, among protestants, is said to be a false opinion, repugnant to some point of doctrine clearly revealed in scripture, and either absolutely essential to the christian faith, or at least of most high importance. 1 Haw. 3.

All old statutes that give a power to arrest or imprison persons for heresy, or introduced any forfeiture on that account, are repealed; yet by the common law an obstinate heretic being excommunicated is still liable to be imprisoned by force of the writ, de excom-

municato capiendo, till he makes satisfaction to the church. 1 Haw. 5.

And if any person having been educated in, or having made profession of the christian religion within this realm, shall be convicted in any of the courts at Westminster, or at the assizes, of denying any of the persons in the Holy Trinity to be God, or maintaining that there are more gods than one, or of denying the truth of the christian religion, or the divine authority of the holy scriptures, he shall, for the first offence, be adjudged incapable of any office; and for the second shall be disabled to sue any action, or to be guardian, executor, or administrator, or take by any legacy or deed of gift, or to bear any office civil or military, or benefice ecclesiastical, for ever, and shall also suffer imprisonment for three years, without bail or mainprise, from the time of such conviction.

HERIOT, signifies a tribute given to the lord for his better preparation towards war. And by the laws of Canute it appears, that at the death of the great men of this nation so many horses and arms were to be paid for as they were in their respective lifetimes obliged to keep for the king's service.

A heriot was first paid in arms and horses; it is now by custom sometimes the best live beast which the tenant dies possessed of; sometimes the best inanimate good, under which a jewel or piece of plate may be included. 2 Black. 422.

As to the several kinds of heriots, some are due by custom, some by tenure, and by reservation on deeds executed within time of memory; those due by custom are the most frequent, and arose by the contract or agreement of the lord and tenant, in consideration of some benefit or advantage accruing to the tenant, and for which an heriot, as the best beast, best piece of household furniture, &c. became due, and belonged to the lord either on the death or alienation of the tenant, and which the lord may seize, either within the manor or without, at his election. Dyer, 199, b.

It has been solemnly adjudged that for an heriot service, or for an heriot reserved by way of tenure, the lord may either seize or distrain; for when the tenant agrees that the lord shall on his death have the best beast, &c. the lord has his election which beast he will take, and by seizing thereof reduces that to his possession, wherein he had a property at the death of the tenant, without the concurring act of any other person; and it is not like the case where the tenant receives 20s. or a robe, for there the lessee has his election which he will pay, and being to do the first act, the lord cannot seize, but must distrain. Plowd. 96.

If the tenure be by rent and heriot service, viz. to have the best beast after the death of the tenant, and the lord distrain for the heriot, he cannot in his avowry shew which was the best beast that he was entitled to, nor of what value it was; for the tenant might have esloined the cattle, and thereby it might have been impossible for the lord to know which was the best beast; and the tenant at his peril is to render the best beast, or sufficient recompense. Cro. Car. 260.

Upon the whole, the custom of the manor is the law of it in all such like cases.

HERISSON, in fortification, a beam armed with a great number of iron spikes, with

their points outwards, and supported by a pivot, on which it turns. These serve as a barrier to block up any passage, and are frequently placed before the gates, and more especially the wicket-doors of a town or fortress, to secure those passages which must of necessity be often opened and shut. See FORTIFICATION.

HERITIERA, a genus of the monœcia monadelphia class and order. The calyx is five-toothed; corolla none. Male, anthers 10, without filaments. Female, germ five; drupes with one globular seed. There is one species, a tree of the East Indies.

HERMÆA, in antiquity, antient Greek festivals, in honour of the god Hermes, or Mercury.

HERMANNIA, a genus of the pentandria order, in the monadelphia class of plants, and in the natural method ranking under the 37th order, columniferae. The capsule is quinquelocular; the petals at the base are semitubulated and oblique. There are 21 species, the most remarkable are,

1. The *lavendulifolia*, which has a shrubby stalk and slender branches, very bushy, about a foot and a half high, small, spear-shaped, obtuse, and hairy leaves, with clusters of small yellow flowers along the sides of the branches, continuing from June to autumn.

2. The *althæifolia* has a shrubby stalk, and soft woolly branches, growing two feet high, with numerous yellow flowers in loose spikes growing at the end of the branches, and making their appearance in July.

3. The *grossularifolia* has a shrubby stalk and spreading branches, growing three or four feet high, with bright yellow flowers coming out in great numbers at the ends of all the shoots and branches in April or May.

4. The *alnifolia* has a shrubby stalk, and branches growing irregularly four or five feet high, with pale yellow flowers in short spikes from the sides and ends of the branches, appearing in April or May.

5. The *hyssopifolia* has a shrubby upright stalk, branching out laterally six or seven feet high, with pale yellow flowers in clusters from the sides of the branches, appearing in May and June. All these plants are natives of Africa, and therefore must be kept in a greenhouse during the winter in this country. They are propagated by cuttings of their young shoots, which may be planted in pots of rich earth any time from April to July.

HERMAS, a genus of the monœcia order, in the polygamia class of plants. The umbel in the hermaphrodite is terminal; there is an universal involucre, and partial ones. The rays of the small umbels are lobed; the central one flower-bearing; there are five petals, and as many barren stamina; the seeds are two-fold, and suborbicular. In the male the lateral umbels have universal and partial involucre; the small umbels are many-flowered; there are five petals, and five fertile stamina. There are five species, herbs of the Cape.

HERMETICAL SEAL, among chemists, a method of stopping glass-vessels, used in chemical operations, so closely, that the most subtle spirit cannot escape through them. It is commonly done by heating the neck of the vessel in a flame, till ready to melt, and then twisting it close together with a pair of pincers. Or, vessels may be hermetically sealed, by stopping them with a glass plug,

Earl and Baroness in her own Right.

Order of the Bath.

Order of St. Patrick.

well luted; or by covering the vessel with another ovum philosophicum.

HERNANDIA, *jack-in-a-box-tree*, a genus of the triandria order, belonging to the monœcia class of plants, and in the natural method ranking under the 38th order, tri-cocœa. The male calyx is tripartite; the corolla tripetalous; the female calyx is truncated, quite entire; the corolla hexapetalous; the plum hollow, and open at the mouth or upper part, with a loose kernel. The species are,

1. The sonora, or common jack-in-a-box, a native of both the Indies. It grows 20 or 30 feet high, with broad peltated leaves, and monœcious flowers, succeeded by a large swollen hollow fruit formed of the calyx; having a hole or opening at the end, and a hard nut within. The wind blowing into the cavity of this fruit makes a very whistling and rattling noise, whence comes the name.

2. The ovigera grows many feet high, with large oval leaves not peltated; and monœcious flowers, succeeded by a swollen fruit open at the end, and a nut within. It is said the sonora in Java affords a sure antidote against poison, if you either put its small roots on the wounds, or eat them; as was discovered to Rumphius by a captive woman in the war between the people of Macassar and the Dutch, in the year 1667. The soldiers of the former always carry this root about them, as a remedy against wounds with poisoned arrows. Both these plants being tender exotics, must be planted in pots of rich earth, and always kept in a hot-house; in which, notwithstanding all the care that can be taken, they seldom flower, and never grow beyond the height of common shrubs, though in the places where they are natives they arrive at the height of trees. They are propagated by seeds procured from the West Indies.

HERNIA. See **MEDICINE** and **SURGERY**.

HERNIARIA, *rupture-wort*, a genus of the digynia order, in the pentandria class of plants, and in the natural method ranking under the eleventh order, holoracœa. The calyx is quinquepartite; there is no corolla; there are five barren stamina, and a monospermous capsule. There are four species, of which the only remarkable one is the glabra, or smooth rupture-wort, a native of many parts of England. It is a low trailing plant, with leaves like the smaller chickweed; the flowers come out in clusters from the side of the stalks at the joints, and are of a yellowish green colour. This plant is a little saltish and astringent. The juice is useful to take away specks in the eye. Cows, sheep, and horses, eat the plant; goats and swine refuse it.

HERON, in ornithology. See **ARDEA**.

HERRING, in ichthyology. See **CLUPEA** and **FISHERY**.

HERRINGS, it is unlawful to buy or sell herrings at sea before the fishermen come into the haven, and the cable of the ship be drawn to the land. 31 Ed. III. c. 2.

No herrings shall be sold in any vessel but where the barrel contains 32 gallons, and half barrel and firkin accordingly; and they must be well packed, of one time's packing and salting, and be as good in the middle as at the ends; on pain of forfeiting 3s. 4d. a barrel.

VOL. I.

Vessels with herrings are to be marked with the quantity and place where packed; and packers are to be appointed and sworn in all fishing ports, and under the penalty of 100l.

HERSE, in fortification, is a lattice or portcullice, made in the form of a harrow, and stuck full of iron spikes. See **FORTIFICATION**.

HESPERIS, *dame's violet*, or *queen's gilliflower*, a genus of the siliquosa order, in the tetradynamia class of plants, and in the natural method ranking under the 39th order, siliquosæ. The petals are turned obliquely; there is a glandule within the shorter stamina; the siliqua almost upright; the stigma forked at the base, connivent, or closing at the top. There are seven species, the most remarkable are,

1. The matronalis, or common sweet-scented garden rocket, having fibrous roots, crowned with a tuft of long, spear-shaped, rough, leaves; upright, single, hairy stalks, two feet high, terminated by large and long spikes of sweet-scented flowers of different colours and properties in the varieties, of which there is a great number. All the varieties of this species are so remarkable for imparting a fragrant odour, that the ladies were fond of having them in their apartments. Hence they derived the name of dame's violet; and bearing some resemblance to a stock-gilliflower were sometimes called queen's gilliflower, but are now most commonly called rocket.

2. The inodora, or scentless rocket, has upright stalks two feet high, all the branches terminated by large spikes of scentless flowers, with obtuse petals, of different colours and properties in the varieties.

3. The tristis, or dull-flowered night-smelling rocket, has upright, bristly stalks, two feet high, spear-shaped pointed leaves, and spikes of pale purple flowers, of great fragrance in the evening.

All the species are hardy, especially the first and second, which prosper in any of the open borders, and any common garden soil; but the third, being rather impatient of a severe frost, and of much moisture in winter, should have a dry warm situation, and a few may be placed in pots, to be sheltered in case of inclement weather. They may be propagated either by seeds, by offsets, or by cuttings off the stalks.

HESSIAN FLY. See **TENTHREDO**.

HETEROGENEOUS NUMBERS, mixed numbers, consisting of integers and fractions.

HETEROGENEOUS QUANTITIES, are those which are of such different kinds, as that one of them taken any number of times, never equals or exceeds the other.

HETEROGENEOUS SURDS, are such as have different radical signs, as $\sqrt[2]{aa}$, $\sqrt[3]{bb}$, $\sqrt[4]{9}$, $\sqrt[5]{18}$, &c. See **SURD**.

If the indices of the powers of the heterogeneous surds be divided by their greatest common divisor, and the quotients be set under the dividends; and those indices be multiplied crosswise by each others quotients; and before the products be set the common radical sign $\sqrt{}$, with its proper index; and if the powers of the given roots be involved alternately, according to the index of each others quotient, and the common radical sign be prefixed before those products, then will those two surds be reduced

to others, having but one common radical sign. As to reduce

$$\sqrt[2]{aa} \text{ and } \sqrt[3]{bb} \quad 1 \times 2 \\ 2)\sqrt[2]{aa} \quad (2 \quad \sqrt[3]{bb} \quad \sqrt[4]{bb} \quad \sqrt[4]{aaaa}$$

HETEROSCHIL. See **GEOGRAPHY**.

HETEROUSIANS, a sect of Arians, who did not believe that the Son of God was of a substance like to that of the Father.

HEUCHERA, in botany, a genus of the pentandria digynia class of plants, the corolla whereof consists of five petals; the fruit is an ovato-accuminated capsule; semibifid, terminating in two reflex points, and containing two cells. There are two species.

HEXACHORD, in antient music, a concord called by the moderns a sixth.

HEXAEDRON, or **HEXAHEDRON**, one of the five regular or Platonic bodies; being indeed the same as the cube; and is so called from its having 6 faces.—The square of the side or edge of a hexahedron, is one-third of the square of the diameter of the circumscribing sphere; and hence the diameter of a sphere is to the side of its inscribed hexahedron, as $\sqrt{3}$ to 1.

In general, if A, B, and C, be put to denote respectively the linear side, the surface, and the solidity of a Hexahedron, or cube, also r the radius of the inscribed sphere, and R the radius of the circumscribed one; then we have these general equations or relations:

$$1. A = 2r = \frac{2}{3}R\sqrt{3} = \sqrt[4]{\frac{1}{6}B}$$

$$= \sqrt[4]{C}.$$

$$2. B = 24r^2 = 8R^2 = 6A^2 = 6\sqrt[4]{C^2}.$$

$$3. C = 8r^3 = \frac{8}{9}R^3\sqrt{3} = A^3 = \frac{1}{6}B\sqrt[4]{\frac{1}{6}B}.$$

$$4. R = r\sqrt{3} = \frac{1}{2}A\sqrt{3} = \frac{1}{2}\sqrt[4]{\frac{1}{6}B}$$

$$= \frac{1}{2}\sqrt{3} \times \sqrt[4]{C}.$$

$$5. r = \frac{1}{2}R\sqrt{3} = \frac{1}{2}A = \frac{1}{2}\sqrt[4]{\frac{1}{6}B} = \frac{1}{2}\sqrt[4]{C}.$$

HEXAGON, in geometry, a figure of six sides and angles; and if these sides and angles be equal, it is called a regular hexagon.

The side of every regular hexagon, inscribed in a circle, is equal in length to the radius of that circle. Hence, it is easy, by laying off the radius six times upon the circumference, to inscribe an hexagon in a circle.

To describe a regular hexagon on a given right line AB (plate Miscel. fig. 123.) draw an equilateral triangle ACB, and the vertex C will be the centre of a circle which will circumscribe the hexagon required ABDEFG.

As 1 is to 1.672, so is the square of the side of any regular hexagon to the area thereof, nearly. Or the side of a hexagon being s , its area will be $= 2.5980762s^2 = \frac{3}{2}s^2 \times \text{tang. } 60^\circ = \frac{3}{2}\sqrt{3}s^2$.

HEXAGON, in fortification, is a place defended by six bastions.

HEXAMETER, in antient poetry, a kind of verse consisting of six feet; the first four of which may be indifferently, either spondees or dactyls; the fifth is generally a dactyl and the sixth always a spondee. Such is the following verse of Horace:

1 2 3 4 5 6
Aut pro | desse vo | lunt, aut | delec | ture po | eta.

HEXANDRIA, in botany, a class of plants, the sixth in order, comprehending all those plants which have hermaphrodite flowers, and six stamina in each.

HIBISCUS, *Syrian mallow*, a genus of the polyandria order, in the monadelphia class of plants, and in the natural method ranking under the 37th order, columniferae.

The calyx is double, the exterior one polyphyllous, the capsule quinquelocular and polyspermous. Of this genus there are 45 species; the most remarkable of which are,

1. The Syriacus, commonly called *althæa frutex*.

2. The *rosa sinensis*, with an arborescent stem, and egg-pointed as wed leaves. It is a native of the East Indies, whence it has obtained the name of China rose; but the seeds having been carried by the French to their West India settlements, it has thence obtained the name of Martinico rose. Of this there are the double and single flowering kinds; the seeds of the first frequently produce plants that have only single flowers, but the latter seldom vary to the double kind.

3. The *mutabilis*, or changeable rose, has a soft spongy stem, which by age becomes ligneous and pithy. It rises to the height of 12 or 14 feet, with heart-shaped leaves. The flowers are produced from the wings of the leaves; the single are composed of five petals, which spread open, and are at first white, but afterwards change to a blush rose-colour, and as they decay turn purple. In the West Indies all these alterations happen on the same day, and the flowers themselves are of no longer duration; but in Britain the changes are not so sudden.

4. The *abelmoschus*, or musk-seeded hibiscus, is a native of the West Indies, where the French cultivate great quantities of it. The stalks and leaves of this sort are very hairy. The flowers are large, of a sulphur colour, with purple bottoms; and are succeeded by pyramidal five-cornered capsules, which open in five cells, filled with large-kidney-shaped seeds of a very musky odour.

5. The *tiliaceus*, or maho-tree, is a native of both the Indies. It rises with a woody, pithy stem, to the height of ten feet, with heart-shaped leaves ending in acute points. The flowers are produced in loose spikes at the end of the branches, and are of a whitish-yellow colour.

6. The *trionum*, Venice mallow, or flower of an hour, is a native of some parts of Italy, and has long been cultivated in the gardens of this country under the name of bladder ketmia.

7. The *esculentus*, or eatable hibiscus, rises to five or six feet; has broad five-parted leaves, and large yellow flowers. The pod or okra is from two to six inches long, and one inch diameter. When ripe it opens longitudinally in five different places, and discharges a number of heart-shaped seeds. These (Dr. Wright informs us) are gathered green, cut into pieces, dried, and sent home as presents, or are boiled in broths or soups for food. It is the chief ingredient in the celebrated pepper-pot of the West Indies, which is no other than a rich olla: the other articles are either flesh meat, or dried fish and capsicum. This dish is very palatable and nourishing. As a medicine, okra is employed in all cases where emollients and lubricants are indicated."

HICKUP, or *hiccough*. See MEDICINE.

HIDE OF LAND, was such a quantity of land as might be plowed with one plough within the compass of a year, or so much as would maintain a family; some call it 60, some 80, and some 100 acres.

HIERACITES, in church history, christian heretics in the third century, so called from their leader Hierax, a philosopher of Egypt; who taught that Melchisedec was the Holy Ghost, denied the resurrection, and condemned marriage, &c.

HIERACIUM, *hawkweed*, a genus of the polygamia æqualis order, in the syngenesia class of plants, and in the natural method ranking under the 49th order, compositæ. The receptacle is naked, the calyx imbricated and ovate; the pappus simple and sessile. There are 55 species, of which the most remarkable are,

1. The *aurantiacum*, commonly called grim the collier, with an upright, single, hairy, and almost leafless stalk, a foot high, terminated by reddish orange-coloured flowers in a corymbus. These flowers have dark oval ash-coloured calyces; whence the name of grim the collier.

2. The *pilosella*, or mouse-ear, has blossoms red on the outside, and pale-yellow within; the cups set thick with black hairs. The flowers open at eight in the morning, and close about two in the afternoon.

3. The *umbellatum* grows to the height of three feet, with an erect and firm stalk, terminated with an umbel of yellow flowers.

HIEROGLYPHICS, in antiquity, mystical characters, or symbols, in use among the Egyptians, and that as well in their writings as inscriptions; being the figures of various animals, the parts of human bodies, and mechanical instruments.

The meaning of a few of these hieroglyphics has been preserved by antient writers. Thus we are told they represented the supreme Deity by a serpent with the head of a hawk. The hawk itself was the hieroglyphic of Osiris; the river-horse, of Typhon; the dog, of Mercury; the cat, of the moon, or Diana; the beetle, of a courageous warrior; a new-born child, of the rising sun; and the like.

HIEROGRAMMATISTS, holy registers, were an order of priests among the antient Egyptians, who presided over learning and religion.

HIGH, in music, an epithet given to any tone or note considerably acute in respect of some other. A word arbitrarily used, and of various meanings, as applied to bass, tenor, or treble voices, or instruments.

HIGHWAY, a public passage for the king's people, whence it is called the king's highway. It seems that antiently there were but four highways in England, which were free and common to all the king's subjects, and through which they might pass without any toll, unless there were a particular consideration for it; all others which we have at this day are supposed to have been made through the grounds of private persons, on writs of *ad quod damnum*, &c. which being an injury to the owner of the soil, it is said they may prescribe for toll, without any special consideration. 3 Bac. Abr. 54.

There are three kinds of ways, a foot-way, a pack and prime way, which is both a horse and foot-way, and a cart-way, which contains the other two. 1 Inst. 56.

But notwithstanding these distinctions, it seems that any of the said ways, which is common to all the king's subjects, whether it leads directly to a market-town, or only from town to town, may properly be called an

highway; and that any such cart-way may be called the king's highway; that a river common to all men may also be called an highway; and that nuisances in any of the said ways are punishable by indictment; otherwise they would not be punished at all: for they are not actionable, unless they cause a special damage to some particular person; because if such action would lie a multiplicity of suits would ensue. 2 Durnf. and East.

But it seems that a way to a parish-church, or to the common field of a town, or to a village which terminates there, may be called a private way, because it belongs not to all the king's subjects, but only to the particular inhabitants of such parish, house, or village, each of which, as it seems, may have an action for a nuisance therein. 1 Haw. 201.

If passengers have used time out of mind, where the roads are bad, to go by outlets on the land adjoining to an highway in the open field, such outlets are parcel of the highway; and therefore if they are sown with corn, and the track foundrous, the king's subjects may go upon the corn. 1 Roll. Ab. 390.

If a way which a man has becomes impassable or very bad, by the owner of the land tearing it up with his carts, by which means it is filled with water; yet he who has the way, cannot dig the ground to let out the water, for he has no interest in the soil. But he may bring his action against the owner of the land for spoiling the way. Godb. 52.

When a private way is spoiled by those who have a right to pass thereon, and not through the default of the owner of the land, it seems that they who have the use and benefit of the way ought to repair it, and not the owner of the soil, unless he is bound thereto by custom or special government. 2 Burn. 483.

Repairing highways. It seems agreed that by the common law the general charge of repairing all highways lies on the occupiers of the lands in the parish wherein they are. But it is said that the tenants of the lands adjoining are bound to scour their ditches. 1 Roll. Abr. 39.

Particular persons may be burdened with the general charge of repairing an highway, in two cases: in respect of an inclosure, or by prescription. As where the owner of lands not inclosed, next adjoining to the highway, incloses his lands on both sides thereof; in which case he is bound to make a perfect good way, and shall not be excused for making it as good as it was at the time of the inclosure, if it was then any way defective; because before the inclosure, when the way was bad, the people for their better passage, went over the fields adjoining, out of the common track, a liberty which the inclosure has deprived them of.

And particular persons may be bound to repair an highway by prescription; and it is said that a corporation aggregate may be compelled to do it by force of a general prescription, that it ought and has used to do it, without shewing that it used to do so in respect of the tenure of certain lands, or for other consideration; because such a corporation, in judgment of law, never dies, and therefore if it was ever bound to such duty, it must continue to be always so: neither is it any plea that such a corporation has always done it out of charity; for what it has always done, it shall be presumed to have been

always bound to do. But it is said that such a general prescription is not sufficient to charge a private person, because no man is bound to do a thing which his ancestors have done, unless it is for some special reason; as having lands descended to him holden by such service, &c. 1 Haw. 202, 203.

It seems certain in all cases whether a private person is bound to repair an highway by inclosure or prescription, that the parish cannot take the advantage of it on the general issue, but must plead it specially; and that, therefore, if to an indictment against the parish for not repairing an highway, they plead not guilty, this shall be intended only that the ways are in repair, but does not go to the right of reparation. 1 Mod. 112.

At common law, it is said that all the county ought to make good the reparations of an highway, where no particular persons are bound to do it, because the whole county have their ease and passage by the said way. Co. Rep. 13.

By the antient common law villages are to repair their highways, and may be punished for their decay; and if any does injury, or straightens the highway, he is punishable in the king's bench, or before the justices of peace in the court leet, &c. Crompt. Jurisd. 76.

Destroying any public turnpike-gate, or the rails or fences thereto belonging, subjects the offender to hard labour for three months, and to be publicly whipped. 1 Geo. II. c. 19.

On conviction at the assizes, the offender may be transported for seven years. And on a second offence, or on demolishing any turnpike-house, he shall be guilty of felony, and transported for seven years. But in both these cases the prosecution must be within six months; and on the convict's returning from transportation he shall suffer death. 5 G. II. c. 33.

Every justice of the peace by the statute, upon his own view, or on oath made to him by the surveyor, may make presentment of roads being out of repair; and thereupon like processes shall be issued as upon indictment.

HIGHWAYMEN, are robbers on the highway; for the apprehending and taking of whom a reward of 40*l.* is given by the statute of 4 and 5 Will. and Mar.

HILLIA, a genus of the monogynia order, in the hexandria class of plants, and in the natural method ranking with those of which the order is doubtful. The calyx is hexaphyllous; the corolla cleft in six parts, and very long; the berry inferior, bilocular, and polyspermous. There are two species, shrubs of Jamaica.

HIP, or **HAW**, in the materia medica, is reputed attenuant and diuretic. There is a very pleasant conserve of hips kept in the shops.

HIPPIA, a genus of the polygamia necessaria order, in the syngenesia class of plants. The receptacle is naked; there is no pappus; the seeds are naked, with very broad margins; the calyx is hemispheric, and subimbricated; the radius consists of 10 corollulae, obscure, and rather cleft into three. There are three species, shrubs of the East Indies and the Cape.

HIPPOBOSCA, a genus of insects of the order diptera. The generic character is, mouth furnished with a bivalve, cylindric,

obtuse, nutant snout; body depressed; feet furnished with several claws. This is not an extensive genus; the European hippobosca, so far as our present entomological information reaches, scarcely affording more than five or six distinct species. Of these the most familiar is the hippobosca equina (see Plate Nat. Hist. fig. 225), or horse-fly, so troublesome to those animals, as well as to cattle, during the decline of summer, by its irritating motion (which is performed in various directions with equal facility), and by the pungent pain which its proboscis excites while in the act of suction. In size it varies indifferent districts, and seems to be largest in the southern climates. It usually, however, measures something more than a quarter of an inch in length, and is of a flattened form, with a rounded abdomen, and moderately broad obtuse wings: its colour is a blackish chesnut, with the thorax speckled with white, and the abdomen marked with obscure variegations of a deeper cast: the skin is of a remarkably strong, or coriaceous nature, since the insect may be pressed strongly between the fingers without being apparently injured. The female of this insect deposits a single egg at distant intervals, and so very large is the egg, as at least to equal, if not in some degree to surpass, the size of the abdomen itself of the parent insect. In reality, however, this seeming egg may be rather considered as a pupa, since it undergoes no farther alteration of form. It continues perfectly inert, and gradually becomes of a brown, and at length of a polished, black colour; and thus commences a genuine or confirmed pupa, which, if opened after a certain period, exhibits the fly in its unadvanced state, and of a white colour. It often lies during the whole winter in this state, the fly emerging in the succeeding summer.

2. *Hippobosca avicularia* much resembles the preceding species, but is considerably smaller, and of a dull-green colour: it is often observed on the bodies of various birds, which it infests in a very troublesome degree.

3. *Hippobosca hirundinis* is equal in size to the *H. avicularia*, and is of a livid-greenish colour, with the abdomen deeply emarginated behind, so as to represent the usual figure of an inverted heart: the wings are of a sharpened or lanceolate form; and the feet, instead of being terminated by two claws only, as in the generality of insects, have six sharp curved divisions. This species is very often observed on the bodies of swallows, swifts, and martins; and may almost always be found in their nests. Its motion, like that of the two preceding kinds, is brisk, but irregular, moving in all directions with equal facility. The egg or pupa of this species is at least as large in proportion to the parent as that of the horse-fly: it gradually changes to a jet-black colour, and the complete fly is usually produced from it in the space of a month.

4. *Hippobosca ovina* is commonly known by the name of the sheep-tick, and is very frequently found imbedded in the wool of those animals. It is of a reddish-brown colour, and differs from the rest of the genus in being entirely destitute of wings. Its pupa is also of reddish-brown colour, exactly oval, and of a shining surface.

All the hippoboscae are remarkably tenacious of life, and the *H. ovina* in particular, which may often be observed in wool that has long been packed into fleeces.

HIPPOCRAMPUS. See **SYNGNETHUS**.

HIPPOCRATIA, a genus of the monogynia order, in the triandria class of plants, and in the natural method ranking with those of which the order is doubtful. The calyx is quinquepartite; the petals five, the capsules three in number, and the latter of an obcordate shape. There are two species, scandent plants of the West Indies.

HIPPOCREPIS, common horse-shoe-vetch, a genus of the decandria order, in the diadelphia class of plants, and in the natural method ranking under the 32 order, papilionaceae. The legumen is compressed and crooked, with many incisions on the interior suture. There are five species, two natives of the warm parts of Europe, and one of Britain. They are all low herbaceous trailing plants, with yellow flowers. They are propagated by seeds; but having no great beauty are seldom kept in gardens.

HIPPOMANE, the manchineel-tree, a genus of the monadelphia order, in the monœcia class of plants, and in the natural method ranking under the 38th order, tricoceae. The male has an amentum and bifid perianthium, without any corolla; the female perianthium is trifid; there is no corolla; the stigma is tripartite; and the plum or capsule tricoceous. See Plate. The species are,

1. The mancinella, with oval sawed leaves, is a native of all the West Indies islands. It has a smooth brownish bark. The flowers come out in short spikes at the end of the branches, but make no great appearance, and are succeeded by fruit of the same shape and size with a golden pippin. The tree grows to the size of a large oak.

2. The biglandulosa, with oblong bay leaves, is a native of South America; and grows to as large a size as the first, from which it differs mostly in the shape of its leaves.

3. The spinosa, with holly leaves, is a native of Campeachy, and seldom rises above 20 feet high; the leaves greatly resemble those of the common holly, and are set with sharp prickles at the end of each indenture. They are of a lucid green, and continue all the year.

These plants being natives of very warm climates cannot be preserved in this country without a stove; nor can they by any means be made to rise above five or six feet high even with that assistance. They are propagated by seeds; but must have very little moisture, or they will certainly be killed by it.

These trees have a very poisonous quality, abounding with an acrid milky juice of a highly caustic nature. Strangers are often tempted to eat the fruit of the first species; the consequences of which are, an inflammation of the mouth and throat, pains in the stomach, &c. which are very dangerous, unless remedies are speedily applied. The wood is much esteemed for making cabinets, book-cases, &c. being very durable, taking a fine polish, and not being liable to become worm-eaten: but as the trees abound with a milky caustic juice already mentioned, fires are made round their trunks to burn out this juice, otherwise those who fell the trees would be in danger of losing their sight by the juice flying in their eyes. This juice

raises blisters on the skin wherever it falls, turns linen black, and makes it fall out in holes. It is also dangerous to work the wood after it is sawn out; for if any of the sawdust happens to get into the eyes of the workmen it causes inflammation; to prevent which they generally cover their faces with fine lawn during the time of working the wood. It is with the juice of this tree that the Indians used to poison their arrows.

HIPPOPHAE, *sea-buckthorn*, a genus of the tetrandria order, in the diœcia class of plants, and in the natural method ranking under the 16th order, calycifloræ. The male calyx is bipartite; there is no corolla; the female calyx is blind; there is no corolla; there is one style, and a monospermous berry. The species are,

1. The *rhamnoides*, with a shrubby stem, branching irregularly eight or ten feet high, having a dark-brown bark.

2. The *canadensis* has a shrubby brown stem, branching eight or ten feet high, with oval leaves, and male and female flowers on different plants. Both these species are very hardy, and may be propagated in abundance by suckers from the roots, by layers, and by cuttings of their young shoots. They are retained in gardens on account of their two-coloured leaves in summer; and in winter on account of the appearance of the young shoots, which are covered with turgid, irregular, scaly buds. Goats, sheep, and horses, eat the first species; cows refuse it.

HIPPOPOTAMUS, a genus of quadrupeds of the order of belluæ. The generic character is, the front teeth of the upper jaw are four, and placed in pairs; those of the lower jaw are prominent, and the intermediate ones are protruded forward; the canine teeth are single, and obliquely truncated; the teats are only two, and placed near the groin. It is a native of the warmer regions of the globe, and is chiefly found in the middle parts of Africa, inhabiting large rivers, and especially such as run through countries overshadowed by large forests; walking about at the bottom, and raising itself at intervals to the surface, for the purpose of respiration. By night it quits its watery residence, to graze in the neighbouring plains, devouring great quantities of herbage, and with its vast teeth destroying the more tender kind of trees and other vegetables. It is sometimes seen even in the sea, at some distance from the mouths of rivers, but this is supposed to be merely for the purpose of exercise; for it will not even drink salt water, and does not prey on fish, or indeed live on any kind of animal food. The general size of the hippopotamus seems to be nearly equal to that of the rhinoceros, and it is sometimes even superior. Its form is highly uncouth; the body being extremely large, fat, and round; the legs very short and thick; the head very large; the mouth extremely wide, and the teeth of vast strength and size, more particularly the tusks or canine teeth of the lower jaw, which are of a curved form: they sometimes measure more than two feet in length, and weigh upwards of six pounds each. The whole animal is covered with short hair, which is much more thinly set on the under parts than on the upper. The hippopotamus when just emerged from the water appears of a palish-brown, or mouse colour, with a

blueish or slate coloured cast on the upper parts; and the belly is flesh coloured, the skin appearing through the hair. When perfectly dry the colour is an obscure brown, without any of the blueish cast. The skin is most excessively tough and strong, except on the belly, where it is considerably softer. Its voice is a peculiar kind of interrupted roar, between that of a bull and the braying of an elephant. When on land it moves in a somewhat slow and awkward manner; but if pursued, can run with considerable speed, and directly plunging into the water sinks to the bottom, and pursues its progress beneath. It is observed to be extremely cautious of making its appearance by day, especially in such places as are much frequented by mankind, scarcely lifting its nose above the surface while breathing; but it is fearless in rivers which run through unfrequented regions, where it is occasionally seen to rush out of the water with sudden impetuosity, trampling down every thing in its way; and at such times is, of course, highly dangerous. It is, however, naturally of a harmless disposition; not attacking other animals, but merely committing havoc in plantations of maize, rice, sugar-canes, &c. and destroying the roots of trees, by loosening them with its vast teeth. It is capable, notwithstanding its great bulk, of swimming very swiftly. Sometimes hippopotami are seen going in herds, or companies, to the distance of some miles from the bank of a river in quest of food. If wounded in the water they become furious, and are said to attack the boats or canoes whence the injury proceeded, and either overturn or sink them, by biting out large pieces from the bottom. The hippopotamus sleeps in the small reedy islets which are found here and there in the rivers it frequents. In such spots it also brings forth its young; having only one at a birth, which it nurses with great care for a considerable time. The young is capable of being tamed, and we are assured by Belon that he saw one so gentle as to shew no inclination to escape, or to do any kind of mischief when let out of the stable in which it was kept.

These animals are said to be most successfully taken by preparing pitfalls for them, of large size, near the rivers. They are also occasionally shot, or killed with harpoons. Their flesh is reckoned good by the Africans, and the fat is said to be a fine kind of lard. But it is chiefly on account of the teeth, and more particularly of the tusks, that this animal is killed; their hardness being superior to that of ivory, at the same time that they are not so subject to become yellow, for which reason they are much used by the dentists. The skin, from its great thickness and strength, when dried, is used by the African nations for bucklers or shields, and is said to be proof against the stroke of a bullet; and indeed the living animal, if shot at any where but on the head or the belly, is scarcely vulnerable, the tough skin causing a bullet to glance from its surface.

The largest female hippopotamus killed by colonel Gordon was about 11 feet long, and the largest male, which always exceeds the female in size, about 11 feet eight inches. Mr. Bruce, however, speaks of hippopotami in the lake Tzana of more than twenty feet long.

The hippopotamus has only a single sto-

mach, and does not ruminate: the stomach, however, has certain cells and divisions, analogous, in some degree, to those of the camel.

M. Sonnini thinks it not improbable that there may in reality exist two species of hippopotamus; one of which confines itself entirely to rivers and fresh waters, and the other to the sea. See Plate Nat. Hist. fig. 226.

HIPPURIS, *mare's-tail*, a genus of the monogynia order, in the monandria class of plants, and in the natural method ranking under the 15th order, inundatæ. There is no calyx, nor any petals; the stigma is simple; and there is one seed. There are three species, one a native of Britain, and which grows in ditches and stagnant waters. The flower of this plant is found at the base of each leaf, and is as simple as can be conceived; there being neither empalement nor blossom; and only one chive, one pointal, and one seed. It is a very weak astrigent. Goats eat it; cows, sheep, horses, and swine, refuse it.

HIRÆA, a genus of the trigynia order, in the decandria class of plants. The calyx is pentaphyllous; the petals roundish and unguiculated; there are three bilabiated seeds. There is one species, a tree of New Spain.

HIRCUS, a goat, in astronomy, a star of the first magnitude, the same with capella. See CAPELLA and ASTRONOMY.

HIRTELLA, a genus of the monogynia order, in the pentandria class of plants, and in the natural method ranking with those of which the order is doubtful. There are five petals; the filaments are very long, persisting, and spiral; the berry is monospermous; the style lateral. There are three species, trees of the West Indies.

HIRUDO, the *leech*, a genus of insects belonging to the order of vermes intestina. The body moves either forward or backward. There are 17 species, principally distinguished by their colour. The most remarkable are the following:

1. The *medicinalis*, or medicinal leech, the form of which is well known, grows to the length of two or three inches. The body is of a blackish-brown colour, marked on the back with six yellow spots, and edged with a yellow line on each side; but both the spots and the lines grow faint, and almost disappear, at some seasons. The head is smaller than the tail, which fixes itself very firmly to any thing the creature pleases. It is viviparous, and produces but one young at a time, which is in the month of July. It is an inhabitant of clear running waters, and is well known for its use in bleeding.

2. The *sanguisuga*, or horse-leech, is larger than the former. Its skin is smooth and glossy; the body is depressed, the back is dusky; and the belly is of a yellowish-green, having a yellow lateral margin. It inhabits stagnant waters.

3. The *geometra*, or geometrical leech, grows to an inch and a half in length; and has a smooth and glossy skin of a dusky-brown colour, but in some seasons greenish spotted with white. When in motion its back is elevated into a kind of ridge; and it then appears as if measuring the space it passed over, like a compass, whence its name. Its tail is remarkably broad; and it holds as firmly by it as by the head. It is common on stones in shallow running waters; and is often

Glaucola austriaca*Gryllus griseus**Gryllus stridulus**Guaiacum officinale**Gymnotus electricus*
Electrical eel*Hamatopus astralegus*
Sea-pie*Aedysarum gyrans**Helix sepium**Halotis tuberculata**Haematites uviformis*

220

*Hippobosca equina**Hemerobius perla*

found on trout and other fish after the spawning season.

4. The muricata, or muricated leech, has a taper body, rounded at the greater extremity, and furnished with two small tentacula, or horns, strongly annulated and rugged upon the rings, the tail dilated. It inhabits the Atlantic ocean, and is by the fishermen called the sea-leech. It adheres to fish, and generally leaves a black mark on the spot.

The mouth of the leech is armed with a sharp instrument that makes three wounds at once, and may be compared to the body of the pump, and the tongue or fleshy nipple to the sucker; by the working of this piece of mechanism the blood is made to rise up to the conduit which conveys it to the animal's stomach, which is a membranaceous skin divided into 24 cells. The blood which is sucked out is there preserved for several months, almost without coagulating, and proves a store of provision to the animal. The nutritious parts, pure and already digested by animals, have no call to be disengaged from the heterogeneous substances: nor indeed is there an anus discoverable in the leech; mere transpiration seems to be all that it performs, the matter fixing on the surface of its body, and afterwards coming off in small threads. Of this an experiment may be tried by putting a leech into oil, where it keeps alive for several days; upon being taken out and put into water, there appears to loosen from its body a kind of slough shaped like the creature's body. The organ of respiration, though unascertained, seems to be situated in the mouth; for if, like an insect, it drew its breath through vent-holes, it would not subsist in oil, as by it they would be stopped up.

It is only the first species that is used in medicine, being applied to the skin in order to draw off blood. With this view they are employed to phlebotomise young children. If the leech does not fasten, a drop of sugared milk is put on the spot it is wished to fix on, or a little blood is drawn by means of a slight puncture, after which it immediately settles. The leech when fixed should be watched, lest it should find its way into the anus when used for the hemorrhoids, or penetrate into the œsophagus if employed to draw the gums, as it would make great havoc in the stomach or intestines. In such a case, the best and quickest remedy is to swallow some salt; which is the method practised to make it loose its hold when it sucks longer than was intended. Salt of tartar, volatile alkali, pepper, and acids, make it also leave the part on which it was applied. Cows and horses have been known to receive them, in drinking, into the throat. The usual remedy is to force down some salt, which makes them fall off. The discharge occasioned by the puncture of a leech is usually of more service than the process itself. When too abundant it is easily stopped with brandy, vinegar, or other styptics, or with a compress of dry linen rag bound strongly on the bleeding orifice.

At Ceylon, travellers who walk bare-legged are molested by the great numbers of leeches concealed under the grass. All leeches vary in their colours at some seasons, but they are generally of a dusky greenish-brown or yellow, and often variegated. They are said to be very restless before a change of weather, if confined in glasses.

HIRUNDO, in ornithology, a genus of birds of the order of passerines. There are 37 species, chiefly distinguished by their colour. The most remarkable are,

1. The rustica, common or chimney-swallow, is distinguished from all the other species by the superior forkiness of its tail, and by the red spot on the forehead and under the chin. The crown of the head, the whole upper part of the body, and the coverts of the wings, are black, glossed with a rich purplish blue, most resplendent in the male: the breast and belly white, and in the male tinged with red. The food of this swallow is the same with the others of its kind, viz. insects. For the taking of these, in their swiftest flight, nature has admirably contrived their several parts: their mouths are very wide to take in flies, &c. in their quickest motions; their wings are long, and adapted for distant and continual flight; and their tails are forked, to enable them to turn the readier in pursuit of their prey. This species is the first comer of all the British hirundines; and appears in general on or about the 13th of April, though now and then a straggler is seen much earlier. This hirundo, though called the chimney-swallow, by no means builds altogether in chimneys, but often within barns and out-houses against the rafters; and so she did in Virgil's time. In Sweden she builds in barns, and is called *ladu swala*, the barn-swallow. Besides, in the warmer parts of Europe there are no chimneys to houses except they are English built: in these countries she constructs her nest in porches, and gateways, and galleries, and open halls. Here and there a bird may affect some odd and peculiar place; but in general with us this species breeds in chimneys, and loves to haunt those stacks where there is a constant fire, no doubt for the sake of warmth. Not that it can subsist in the immediate shaft where there is a fire, but prefers one adjoining to that of the kitchen, and disregards the perpetual smoke of that funnel. Her nest consists, like that of the house-martin, of a crust or shell composed of dirt or mud, mixed with short pieces of straw to render it tough and permanent; with this difference, the shell of the martin is nearly hemispheric, that of the swallow is open at the top, and like half a deep dish: this nest is lined with fine grasses, and feathers which are often collected as they float in the air.

This bird lays from four to six white eggs, dotted with red specks; and brings out her first brood about the last week in June, or the first week in July. The progressive method by which the young are introduced into life is very curious: first, they emerge from the shaft with difficulty enough, and often fall down into the rooms below; for a day or two they are fed on the chimney-top, and then are conducted to the dead leafless bough of some tree, where, sitting in a row, they are attended with great assiduity, and may be then called perchers. In a day or two more they become flyers, but are still unable to take their own food; therefore they play about near the place where the dams are hawking for flies; and when a mouthful is collected, at a certain signal given, the dam and the nestling advance, rising towards each other, and meeting at an angle; the young one all the while uttering such a little quick note of gratitude and complacency,

that a person must have paid very little regard to the wonders of nature that has not often remarked this feat. The dam betakes herself immediately to the business of a second brood as soon as she is disengaged from her first; which she at once associates with the first broods of house-martins, and with them congregates, clustering on sunny roofs, towers, and trees. This hirundo brings out her second brood towards the middle and end of August.

Each species of hirundo drinks as it flies along, sipping the surface of the water; but the swallow alone, in general, washes on the wing, by dropping into a pool for many times together: in very hot weather house-martins and bank-martins dip and wash a little. The swallow is a delicate songster, and in soft sunny weather sings both perching and flying; on trees in a kind of concert, and on chimney-tops. Horsemen on wide downs are often closely attended by a little party of swallows for miles together, which plays before and behind them, sweeping around, and collecting all the sculking insects that are roused by the trampling of the horses' feet: when the wind blows hard, without this expedient, they are forced to settle to pick up their lurking prey.

This species feeds much on little coleoptera, as well as on gnats and flies; and often settles on dug-ground, or pats, for gravel to grind and digest its food. Mr. White informs us, that before they depart, for some weeks, to a bird, they forsake houses and chimneys, and roost in trees; and usually withdraw about the beginning of October; though some few stragglers may be seen at times till the first week in November. Mr. Pennant says, that for a few days previous to their departure, they assemble in vast flocks on house-tops, churches, and trees, whence they take their flight. They are supposed to take up their winter-quarters in Senegal and parts adjacent, and seem to possess in turn the whole of the old continent, being known from Norway to the Cape of Good Hope on the one hand, and from Kamtschatka to India and Japan on the other. They are also found in all parts of North America, migrating north and south, as with us.

2. The esculenta, or edible swallow, according to Buffon, is less than the wren, and only two inches and a quarter in length. The bill is black; the upper parts of the body are brown, the under whitish; the tail is forked, and each feather of it is tipped with white; the legs are brown. See Plate Nat. Hist. fig. 228.

The most curious part of the natural history of this bird consists in the nest, which is composed of such materials as render it not only edible, but one of the greatest dainties of the Asiatic epicures.

These nests are found in vast numbers in certain caverns, in various isles in the Soolo Archipelago, situated between longitude 117 and 120, latitude 5 and 7; particularly in three small isles, or rather rocks; in the caverns of which the nests are found fixed to the sides in astonishing numbers. Of these nests, it is said the Dutch alone export from Batavia 1000 pickles, upwards of 1300lb. English weight, every year, which are brought from the isles of Cochin China, and those lying to the east of them.

3. The urbica, or martin, is inferior in size to the chimney swallow, and its tail much less forked. The head and upper part of the body, except the rump, are black, glossed with blue; the breast, belly, and rump, are white; the feet are covered with a short white down. This is the second of the swallow kind that appears in our country. They begin to appear about the 16th of April. About the middle of May, if the weather is fine, the martin begins to think in earnest of providing a mansion for its family. As this bird often builds against a perpendicular wall without any projecting ledge under, it requires its utmost efforts to get the first foundation firmly fixed, so that it may safely carry the superstructure. That this work may not, while it is soft and green, pull itself down by its own weight, the provident architect has prudence and forbearance enough not to advance her work too fast; but by building only in the morning, and by dedicating the rest of the day to food and amusement, gives it sufficient time to dry and harden. By this method in about 10 or 12 days is formed an hemispheric nest, with a small aperture towards the top, strong, compact, and warm, and perfectly fitted for all the purposes for which it was intended. But then nothing is more common than for the house-sparrow, as soon as the shell is finished, to seize on it as its own, to eject the owner, and to line it after its own manner. At first, when the young are hatched, and are in a naked and helpless condition, the parent birds, with tender assiduity, carry out what comes away from their young. Was it not for this affectionate cleanliness the nestlings would soon be burnt up and destroyed in so deep and hollow a nest by their own caustic excrement. As soon as the young are able to shift for themselves, the dams immediately turn their thoughts to the business of a second brood: while the first flight, shaken off and rejected by their nurses, congregate in great flocks, and are the birds that are seen clustering and hovering on sunny mornings and evenings on round towers and steeples, and on the roofs of churches and houses. As the summer declines the congregating flocks increase in numbers daily, by the constant accession of the second broods, till at last they swarm in myriads upon myriads round the villages on the Thames, darkening the face of the sky as they frequent the aits of that river, where they roost. They retire in vast flocks together about the beginning of October. Unless these birds are very short-lived indeed, or unless they do not return to the district where they are bred, they must undergo vast devastations somehow, and somewhere; for the birds that return yearly bear no manner of proportion to the birds that retire.

4. The riparia, sand-martin, or shore-bird, is $4\frac{3}{4}$ inches in length, with the whole upper parts of the body of a mouse colour, the throat and under parts white, the bill and legs blackish. It is common about the banks of rivers and sand-pits, where it terebrates a round and regular hole in the sand or earth, which is serpentine, horizontal, and about two feet deep. At the inner end of this burrow the bird deposits her rude nest, consisting of fine grasses and feathers, usually goose-feathers, very inartificially laid together.

5. The apus, or swift, is a large species,

being near eight inches long, with an extent of wing near 18 inches, though the weight of the bird is only one ounce. Their feet are so small, that the action of walking and rising from the ground is extremely difficult; but nature has made it full amends, by furnishing it with ample means for an easy and continual flight. It is more on the wing than any other swallow; its flight is more rapid, and that attended with a shrill scream. It rests by clinging against some wall, or other apt body; whence Klein styles this species *li-rundo muraria*. It breeds under the eaves of houses, in steeples, and other lofty buildings; and makes its nest of grasses and feathers. The feet of this species are of a particular structure, all the toes standing forward: the least consists of only one bone; the others of an equal number, viz. two each, in which they differ from those of all other birds: a construction, however, nicely adapted to the purposes in which their feet are employed. See Plate Nat. Hist. fig. 227.

The swift is a summer inhabitant of these kingdoms. It comes the latest, and departs the soonest, of any of the tribe; not always staying to the middle of August, and often not arriving before the beginning of May.

6. The melba, or white bellied swift, is in length eight inches and a half, and weighs two ounces five drams.

7. The cayennensis, or white coloured swallow, is about the size of the martin: the head and bill are black; the chin and throat white, passing from the last in a narrow collar round the neck: between the bill and eye is a streak of white, which forks off into two, one passing a little above, and the other a little way beneath, the eye: the rest of the plumage is black, with a gloss of violet; but the greater coverts, nearest the body, are brown edged with white. This bird makes its nest in the houses at Cayenne. It is of a large size, in shape of a truncated cone; five inches one way by three the other, and nine inches in length. It is composed of the down of dog's-bane, well woven together; the cavity divided obliquely about the middle, lengthways, by a partition, which spreads itself over that part of the nest where the eggs lie, which is pretty near the base: a small parcel of the same soft down, forming a kind of plug, is placed over the top, serving to keep the young brood from the impression of the air, from which we may suppose them to be very tender.

By the myriads of insects which every single brood of swallows destroys in the course of a summer, they defend us in a great measure from the personal and domestic annoyance of flies and gnats; and, what is of infinitely more consequence, they keep down the numbers of our minute enemies, who, either in the grub or winged state, would otherwise render the labours of the husbandman fruitless. Since then swallows are guardians of our corn, they should every where be protected by the same popular veneration which in Egypt defends the ibis, and the stork in Holland. We more frequently hear of unproductive harvests on the Continent than in this country; and it is well known that swallows are caught and sold as food in the markets of Spain, France, and Italy. In England we are not driven to such resources to furnish our tables. But what apology can be made for those, and many there are, whose

education and rank should have taught them more innocent amusements, who wantonly murder swallows, under the idle pretence of improving their skill in shooting game? Setting aside the cruelty of starving whole nests of young by killing the dam; those who follow this barbarous diversion would do well to reflect, that by every swallow they kill, they assist blasts, mildews, and vermin, in causing a scarcity of bread. Every lord of a manor should restrain his game-keeper from this execrable practice; nor should he permit any person to sport on his lands who does not refrain from it.

HISPA, in zoology, a genus of insects belonging to the coleoptera order, the characters of which are these: the antennæ are fusiform, growing gradually larger from each extremity towards the middle, and are situated between the eyes; the thorax and elytra are covered with protuberances or spines. The larva of this insect seems to be yet wholly unknown. There are but two species of the perfect animal met with in Europe; one of which, the atra, is found in Britain, and is all over of a deep unpolished black, and has the upper part of its body entirely covered with long and strong spines, which render it bristly like the shell of a chestnut. There is even a spine at the base of the antennæ; the thorax has a row set transversely, which are forked; and the elytra are furnished with a very great number that are single. Its being thus covered with spines makes it resemble a hedge-hog in miniature. It is rather hard to catch, letting itself fall down to the ground as soon as approached. It bears its antennæ upright before it. See Plate Nat. Hist. fig. 229.

HISTER, a genus of insects of the coleoptera order. The generic character is, antennæ headed by a somewhat solid tip, lowest joint compressed and decurved; head retractile; mouth forcipated; wing-sheaths shorter than the body; fore-legs toothed.

The most common European species of this genus is the hister unicolor of Linnaeus. It is entirely of a glossy coal-black colour, and of a slightly flattened shape, varying considerably in size, but usually measuring about the third of an inch in length, and is often seen in gardens, sandy fields, &c. Its larva seems to be unknown.

Hister quadrimaculatus, has much the appearance of a small beetle; its shape is strongly convex, and its colour black, with two dull-red bars on each wing-shell, viz. one at the base, and the other, smaller, at the tip. It is found about dunghills, &c.

HISTORY, civil. History, in its simplest definition, implies the mere narration of events and facts; but when placed in its true dignity, it is something more than this, it is philosophy "teaching by examples." The study of it is more or less the employment of all persons of reading and education; and the composition of it was the earliest use that was made of letters, since the first poems were historical: it is calculated for the use of all ranks and all professions in life, and places the reader of its events as a spectator out of all hazards, who may reap wisdom from the danger of others, and foretell, to a certain extent, the future by the past.

The general uses of history are exhibited by Dr. Priestley under three heads: 1. He says, history serves to amuse the imagination,

and interest the passions in general. 2. It improves the understanding: and, 3. It tends to strengthen the sentiments of virtue. In the first of these views we find history has a great advantage over every work of fiction: for we consider it as the voice of truth. The second has been aptly illustrated by Bolingbroke, who observes that "He who studies history as he would philosophy, will distinguish and collect certain general principles and rules of life and conduct, which always must be true, because they are conformable to the invariable nature of things; and by doing so he will soon form to himself a general system of ethics and politics on the surest foundations, on the trial of these principles and rules in all ages, and on the confirmation of them by universal experience." And the third is still more evident, from the very light in which characters and events are seen in it. Fame is found just to the dead, however partial to the living.

The sources of history form another topic of enquiry. The earliest of these was undoubtedly tradition; the next, perhaps, poetical narrations; which, though often mixed with the absurdities of fable, contain facts and characters of ancient life that illustrate the manners of the early ages. Coins, medals, and inscriptions, the works of artists of all kinds, and sometimes even rude heaps, are other monuments, whose collateral aids are equally necessary with the astronomical mediums employed by Newton, in the correction of chronology. In later times, as political society increased, the archives and laws of states perpetuated information in a more certain and extended form. The correct knowledge of events was easily obtained. Private experience could be joined to the information contained in public annals; and fair topics were presented to the pen of every man who proposed to himself the task of an historian.

In regard to what is necessary or useful to be known previous to the study of history, it is proper to observe that it must be taken in very different degrees of extent, according to the views with which history is read; and these depend very much upon the age and situation of the person who applies to it. But whoever proposes to study history scientifically, must come to the reading of it furnished with the first principles of certain sciences. If not the knowledge, at least a general idea of the principles of human nature, will be an excellent guide to us in judging of the consistency of human characters, and of what is within and what is without the reach of human powers. Philosophical knowledge, in general, will be found of the most extensive use to all persons who would examine with accuracy the achievements of ancient nations in peace or war, or who would thoroughly weigh the accounts of any thing in which the powers of nature are employed. But those sciences which are of the most constant and general use are geography and chronology. A knowledge of the situation and relative magnitude of the several countries of the earth, assists and affords clear and distinct ideas of events; and a general comprehension of the current of time enables us distinctly to trace their dependence on each other.

Beside these, however, there are other helps. Obvious advantages will attend the use of a good compendium of general his-

tory, previous to the study of any particular portion. The earliest epitome was the *Chronicon Carionis*, printed at Wittenberg, 1532; but the most celebrated are, Turselin's, Bossuet's, and Baron Holberg's; the last of these was translated into English by Mr. Gregory Sharpe. Of chronological tables the best and most completely useful are Blair's; and of the charts of history, Dr. Priestley's. These shew at once the reference which the history of one country bears to that of another.

The misapplication to which history is liable, evinces the necessity of prosecuting the study of it according to a regular plan. To those who can reach its sources these directions may be serviceable: principally obtained from Dr. Priestley.

The sacred history may properly be said to stand alone: it is not only the most certain, but exhibits the continuation of the true religion uninterrupted from the creation of the world, and therefore ought to form the ground-work of our study.

The oldest history extant, next to the historical books of the Old Testament is that of Herodotus, who flourished about four hundred and fifty years before the christian era, a little after the invasion of Greece by Xerxes. His history comprises probably every thing he had an opportunity of learning concerning the history of the Lydians, Ionians, Lycians, Egyptians, Persians, Greeks, and Macedonians: computing from the earliest of his accounts to the latest, his history may be reckoned to commence about seven hundred and thirteen years before Christ, and to reach to about four hundred and seventy-nine before Christ; a period of about two hundred and thirty-four years.

Next to Herodotus, Thucydides is to be read; whose history reaches to the 21st year of the Peloponnesian war, the history of which is completed in the first and second books of Xenophon's History of Greece. After this, the student may proceed to the expedition of Cyrus, and the return of the Greeks: and then go back to the remaining books of Xenophon's history. The fifteenth and sixteenth books of Diodorus Siculus contain the histories of Greece and Persia from the battle of Mantinea to the beginning of the reign of Alexander the Great, in the year 336 before Christ. For the history of Alexander, Arrian, Quintus Curtius, and the tenth and eleventh books of Justin must be referred to. The eighteenth, nineteenth, and twentieth books of Diodorus Siculus contain the History of Greece from the year 323 before Christ, to the year 301: the thirteenth, fourteenth, and fifteenth books of Justin will complete the period; and those which follow to the twenty-ninth inclusive, carry on the history to about the year 195 A.C. Lastly, in the regular order of history read the thirteenth book of Justin, and all that follow to the two last, which completes the History of Greece till it mixes with that of the Romans.

The lives of illustrious men by Plutarch and Cornelius Nepos, form an excellent supplement to the regular historians.

Of the above works, which contain not only the History of Greece, but that of all the nations of the world known to the historians, Justin, Quintus Curtius, and Cor-

nelius Nepos, only, are in Latin; the rest are in Greek.

The following course of Roman History comprehends all that is to be learnt now of the subsequent Antient History of all other nations. The writer who treats of the early part of the Roman history, in the fullest and most satisfactory manner, is Dionysius of Halicarnassus, a rhetorician as well as an historian: the remains of his works which originally brought the History of Rome to the beginning of the first Punic war, end at this time with the year 341 before Christ, the time when the consuls resumed the chief authority in the republic after the dissolution of the decemvirate: so that to complete the period we must go to the three first books of Livy, whose history to the tenth book inclusive, brings that of Rome to the year 451, of the building of the city, or 292 before Christ. To supply the chasm between the tenth and twentieth books of Livy, read Polybius, the seventeenth, eighteenth, twenty-second, and twenty-third books of Justin, and Appian's Punic and Illyrian wars; and afterwards the remainder of Livy from the twenty-first book to the end, which brings the history to 166 years before Christ. Sallust's History of the War of Jugurtha and the Catalinarian conspiracy, are the next books to be proceeded to: they are all which remain to us of his works. The Commentaries of Cæsar, and Cicero's Epistles to Atticus, are the next works to be consulted, followed by the remains of Dio Cassius, and the Compendium of Velleius Paterculus. Suetonius's Lives of the Cæsars, and the Works of Tacitus, close the list of Roman historians of the greatest eminence. Those who are called the writers of the brassen or iron age deserve a slighter mention. The principal of these are, Xiphilin, Herodian, The Historia Augusta Scriptores, Zozimus, Ammianus Marcellinus, Paulus Deaconus, and Procopius; the last four, however, may be omitted; and Nicetas Acominatus and Nicephorus Gregoras, followed by Joannes Cantacuzenus, substituted in their room. Laonicus Chalcondiles brings up the conclusion of the Eastern Empire, in the year 1453, when Constantinople was taken by Mahomet II.

To enumerate all the modern compilations of ancient history which may be serviceable to those who cannot make their searches in the original authors would be endless. That of Rollin must not be passed over. The most complete body of history, however, ancient and modern, is the Universal: which has references to the original writers for almost every paragraph of information. Gillies and Mitford have written Histories of Greece, and Hooke is by far the most preferable among the compilers of the Roman history.

Having been thus particular on the subject of ancient history, we shall go on to the enumeration of those sources from which the last materials are derived for English history; and then proceeding to the other countries of modern Europe, make a slight mention of the best historians of each.

The earliest accounts of Britain are to be found among the Romans; and principally in the works of Julius Cæsar, Dio Cassius, and Tacitus. Livy and Fabius Rusticus were others who wrote expressly on its his-

tory; but their works have perished in the general wreck of ancient literature.

The most ancient of our native historians, now extant, says bishop Nicholson, is Gildas, a monk of Bangor, who lived about the middle of the sixth century; a sorrowful spectator of the miseries and almost utter ruin of his countrymen, by a people under whose banners they hoped for peace. The title of his work was, "*De Excidis Britannie*." The next historian of note was Nennius, who is often confounded with Gildas: his work, which has gone by different names, was printed by Gale under that of "*Historia Britonum*." If we except a supplement to these writers, in the laws of Hoel Dha, we have nothing more of early British history. Geoffrey of Monmouth's work, which was written at a subsequent period, is nothing more than a romance.

For the history of the Saxon times we have better materials, the oldest of which, perhaps, that are now preserved, are in the Saxon Chronicle, printed from several manuscripts by bishop Gibson. Next to this Bede's Ecclesiastical History may be placed, and the Life of Alfred by Asser of St. David's.

Only two Danish historians, says bishop Nicholson, are necessary to the English antiquary's library; Saxo Grammaticus and Sweno Agonis.

The first English historian after the Norman Conquest, was Ingulph, abbot of Crowland, whose history extends from the year 626 to 1089. That portion of Marianus Scotus's history which relates to Britain never has been printed. Florence of Worcester's, who died 1119, is more full.

Eadmer's work, published by Mr. Selden, contains the history of the two Williams and Henry the First, from 1066 to 1122, and is a work of very good authority.

William of Malmesbury was the next historian, whose book "*De Gestis Rebus Anglorum*," is one of the most faithful of our numerous annals: it begins with the first arrival of the Saxons, and is continued to the death of Stephen. The other historians of the twelfth century were, Simeon Dunelmensis, Henry of Huntingdon, and William de Neuburg.

Gervase of Canterbury's history, of which a fragment only is left, is the earliest of the thirteenth century: his chief contemporary was Hoveden, who seems to have been chaplain to king Henry the Second. Ralph de Diceto, Walter of Coventry, and Matthew Paris, were others. There were likewise a few meaner historians, whose names it is not necessary to repeat.

The principal writers of the fourteenth century were, Wikes, Trivet, John Brompton, Higden, John of Timmouth, Matthew of Westminster, and Knighton: the last but one of whom is often called Florilegus.

The first and principal writer of the fifteenth century was Froissart, whose work has been so carefully translated by Mr. Johnes. It affords the best history of the English Nation during the reigns of Edward the Third and Richard the Second. Thomas de Walsingham is the next writer of credit, succeeded by John Harding, Caxton, and Rouse.

Fabian's Chronicle is the first work of

consequence in the sixteenth century, and is said to have given great offence to Wolsey. Polydore Virgil's history is not believed to have been so faithful; though greater merit is attributed to the works of Hall and Hollinshed.

The industrious Stowe was the first writer among the historians of the seventeenth century: the next of eminence was Daniel Speed, sir Richard Baker, Sandford, Brady, Echard and Tyrrel, are others, whose names only it is quite sufficient to enumerate.

In the last century, bishop Burnet, Carte, Kennet, Tindal, Hume, Smollet, Macaulay, and Henry, are historians too well known, to need either comment or commendation here.

In regard to the writers of particular histories of the kings with whom they were contemporary, it may be sufficient to enumerate the following: William the Conqueror's life was written by William of Poitiers; king Stephen's memoirs, by Richard Prior of Hexham, printed among the decem-scriptores; Richard the First's Expedition into the Holy Land, was celebrated by Joseph of Exeter, or Iscanus; the Life of Edward the Second by sir Thomas de la More: Henry the Fifth's by some one under the name of Titus Livius: and that of Edward the Fifth, with a part of the History of Richard the Third, by sir Thomas More; Henry the Eighth's Reign, by lord Herbert of Cherbury; and Elizabeth's by Camden. Those of a later period, perhaps, are hardly entitled to so much credit for impartiality.

The historians of other particular countries may be mentioned in a briefer manner; enumerating such only as a reader may refer to when inquiring into facts. In regard to France, after mentioning the *Chroniques de St. Denis*, the *Annales Francorum*, with the works of Monstrelet, Mezeray, Daniel and Garnier, and Henault's Abridgment, we need only mention two of the most comprehensive bodies of French history, "*Duchesne's Historiæ Francorum Scriptores*;" and "*Bouquet's Recueil des Historiens des Gaules et de la France*," in thirteen volumes folio. For the general history of Italy, Guicciardini's work is undoubtedly the best, not only for its accuracy but its style; though Brunsion's and Capriata's works are much esteemed for their veracity. To those who make a deep search, the "*Rerum Italianarum Scriptores*," by Muratori, will be useful.

For the separate states of Italy, Giannoni's History of Naples, Machiavel's *Historia Florentina*, and the "*Historia Veneziani*." For Switzerland, the "*Helvetic Confederacy*" by Mr. Planta, may be referred to: for Holland, Le Clerc's "*Provinces Unies*," 1728. Among the writers of German history, the "*Germani Scriptores*" of Pistorius, Urstilius, Freher, and Reuber, may be mentioned; the writers on ancient Germany by Schard; the *Scriptores Rerum Brunsvicensium*; and Mascou's history of the Germans.

The most valuable history of Spain is Mariana's, first published in 1592; the best edition of which, continued to a late period, was published at Valencia 1783. Beside this, Curita's "*Annales de Arragon*" may be consulted with the "*Annales de Cattaluna*." The earliest materials for Portuguese history are to be found among the *Scriptores Rerum Hispaniarum*. The first historian

whom Meusel mentions is Laimund de Ortega: but one of the most valuable and industrious was Bernard de Brito, who published the two first parts of the "*Monarchia Lusitana*," in 1597 and 1609; which was continued as far as an eighth part, in 1729. Others are, Meneze's *Historia de Portugal*, printed at Lisbon in two volumes, folio, 1679 and 1698; La Clede's *Histoire de Portugal*, Par. 1735; and the elaborate history of Gebauer, in German, Leipsig, 1759. On Sweden, Crusius's "*Annales Suevicæ*," 1596, and Puffendorf "*de Rebus Suevicis*," 1686, will be found works of considerable consequence. On Norway, Forfæus's "*Historia Rerum Norvegicarum*." On Denmark, Cragius's "*Annales Danicæ*;" Mallet's "*Histoire de Dannemarc*," and Langebek's "*Scriptores Rerum Danicarum*;" and on Russia, "*Rerum Muscoviticarum Scriptores*," 1600, folio, and Levesque's "*Histoire de Russie*," 1800. Those who would gain a more particular knowledge of the characters which the principal of these historians bear, may consult the works of Wheare and Rawlinson on History.

There are, however, some particular histories, which are so excellently written, that no person of a liberal education should neglect becoming acquainted with them. Under this character we may comprehend all the works of Tacitus, which now remain to us: in his writings every phrase is a maxim; the narrative goes on with rapidity; while all his characters are drawn with a more profound knowledge of human nature than those of any historian who went before him; his very brevity is pregnant. Thuanus's history of his own times is a work almost equal to any production of the classic ages. Guicciardini's History of Italy: Davila's of the Civil Wars of France; Bentivoglio's of those of the Netherlands; and Giannoni's History of Naples, deserve a similar character, as well as the elegant history of our own country by Hume. No writer whatever, says Dr. Priestley, can excel Vertot in the happy art of making history entertaining.

There are also periods of history more particularly deserving of a close attention. Among these the connection of sacred and profane history in the succession of the four great monarchies, stands foremost. Another period is that which comprises the history of the Grecian commonwealths, in which the peculiar evils and advantages of a popular government are exhibited with clearness. The rise and declension of the Roman empire is another object for extensive contemplation, as well as the foundation of the present European governments, and the restoration of learning.

We have now only to add a few words on the particular duty of the historian; the model for whom is preserved among the works of Cicero. It is the first law of history, he says that the writer should neither dare to advance what is false, nor to suppress what is true; that he should relate the facts with strict impartiality, free from ill-will or favour; that his narrative should distinguish the order of time, and when necessary, give the description of places; that he should unfold the statesman's motives, and in his account of the transactions and the events, interpose his own judgment; and should not only relate what was done, but how it was done; and

what share, chance, or rashness, or prudence, had in the issue; that he should give the characters of the leading men their weight and influence, their passions, their principles, and their conduct through life. In addition to these, Tacitus gives another rule: "Præcipuum munus annalium reor, ne virtutes sileantur, utque pravis dictis factisque exposititate et infamia metus sit:" that it is incumbent on the writer to rejudge the actions of men, to the end that the good and worthy may meet with the reward due to eminent virtue, and that pernicious citizens may be deterred by the condemnation that waits on evil deeds at the tribunal of posterity. In this consists the chief part of the historian's duty.

Let it be remembered that in this country, it is an indispensable duty of every man of liberal birth, to be acquainted in a certain degree with the science of politics. History is the school of politics: it unfolds to us the springs of human affairs; the causes of the rise, grandeur, revolutions, and fall of empires. It points out the reciprocal influence of government and of national manners: it dissipates prejudices, nourishes the love of our country, and directs to the best means of improvement. It illustrates equally the blessings of political union and the miseries of faction.

As to the events that stand recorded in history, says lord Bolingbroke, we see them all, we see them as they followed one another, or as they produced one another, causes or effects, immediate or remote. We are cast back, as it were, into former ages; we live with the men who lived before us, and we inhabit countries that we never saw. Place is enlarged, and time prolonged in this manner; so that the man who applies himself early to the study of history may acquire in a few years, and before he sets his foot abroad in the world, not only a more extended knowledge of mankind, but the experience of more centuries than any of the patriarchs saw. The events we are witnesses of in the course of the longest life, appear to us very often original, unprepared, simple, and unrelative; they appear such very often, are called accidents, and looked upon as the effects of chance: experience can carry us no farther, for experience can go a very little way back in discovering causes; and effects are not the objects of experience till they happen. Hence many errors in judgment, and by consequence in conduct, necessarily arise; and here too lies the difference we are speaking of between history and experience: the advantage on the side of the former is double. In ancient history the examples are complete, which are incomplete in the course of experience; experience is doubly defective; we are born too late to see the beginning, and we die too late to see the end of many things. History supplies both those defects. Modern history shews the causes when experience presents the effects alone; and ancient history enables us to guess at the effects when experience presents the causes alone.

HITCH, in the sea-language, is to catch hold of any thing with a hook or rope, and by this means to hold it fast: thus when a boat is to be hoisted in, the sailors say, hitch the tackles into the ring-bolts of the boat; and when they are about to weigh

anchor, hitch the fish-hook to the fluke of the anchor.

HIVE, in country affairs, a convenient receptacle for bees. See **APIS**.

HOARSENESS. See **MEDICINE**.

HODMAN, an appellation given to a young student admitted into Christ's College, Oxford, from Westminster-school.

HOE, a husbandman's tool, somewhat like a cooper's adze to cut up weeds in gardens, fields, &c. This instrument is of great use, and ought to be much more employed than it is in hacking and clearing the several corners and patches of land in spare times of the year, which would be no small advantage to it.

HOEING, in the new husbandry, is the breaking or dividing the soil by tillage while the corn or other plants are growing thereon. It differs from common tillage (which is always performed before the corn or plants are sown or planted) in the time of performing it; and it is much more beneficial to the crops than any other tillage. This sort of tillage is performed various ways, and by means of different instruments.

HOG. See **SUS**.

HOG, on board of a ship, is a sort of flat scrubbing broom, formed by inclosing a number of short twigs of birch or such wood between two pieces of plank fastened together, and cutting off the ends of the twigs. It is used to scrape the filth from a ship's bottom under water, particularly in the act of boot-topping. For this purpose they fit to this broom a long staff with two ropes; one of which is used to thrust the hog under the ship's bottom, and the other to guide and pull it up again close to the planks.

HOGSHEAD, in commerce, a measure of capacity, containing sixty-three gallons.

HOLCUS, Indian millet or corn; a genus of the monocœcia order, in the polygamia class of plants; and in the natural method ranking under the 4th order, gramina. The calyx of the hermaphrodite is an uniflorous or biflorous glume; the corolla is a glume with an awn; there are three stamina, two styles, and one seed. The male calyx is a bivalved glume; there is no corolla, but three stamina.

Of this genus there are fifteen species, two of which are natives of Britain. The most remarkable of these is the lanatus, or creeping soft-grass of Hudson. The most remarkable of the foreign species is the sorghum, or Guinea-corn. The stalks are large, compact, and full eight feet high. In Senegal the fields are entirely covered with it. The negroes, who call it guarnot, cover the ears when ripe with its own leaves to shelter it from the sparrows, which are very mischievous in that country. The grain made into bread, or otherwise used, is esteemed very wholesome. With this the slaves in the West Indies are generally fed, each being allowed from a pint to a quart every day. The juice of the stalks is so agreeably luscious, that, if prepared as the sugar-canes, they would afford an excellent sugar.

HOLOCENTRUS. *Holocentrus*, a genus of the order thoracici; the generic character is, habit of the genus perca; gill-covers scaly, serrated, and aculeated; scales in most species, hard and rough. There are 35 species, the principal of which are:

1. *Holocentrus sogo*, a highly beautiful

species: general length about a foot; habit somewhat resembling that of a carp, but of a squarer form, growing suddenly slender near the tail; eyes very large and gold-coloured; scales large and denticulated at the edges; tail very much forked. Native of the Mediterranean, Indian, and American seas, and considered as an excellent fish for the table.

2. *Holocentrus schraetzer*: length about ten inches; shape somewhat lengthened; head destitute of scales, for which reason this species is by Dr. Bloch arranged under a distinct genus by the name of *gymnocephalus*: scales rather small than large; tail slightly divided; lowest of the longitudinal lines composed of a row of spots; dorsal fin spotted with black; native of the Danube and its tributary streams; in considerable esteem as an article of food.

3. *Holocentrus decussatus*, decussated holocentrus: length about twelve inches; back dusky brown; sides marked by two longitudinal brown stripes from the gills to the tail, and by seven transverse ones, each continued to some little distance into the dorsal fin, which is white or pale; scales middle-sized; eyes blue; tail brown, and slightly lunated.

4. *Holocentrus calcarifer*, spur-gilled holocentrus: length about a foot; habit that of a carp, but rather more lengthened in proportion; body marked by dusky lines along each row of scales; anterior gill-covers furnished with four strong sharp spines, so placed as to bear some resemblance to the rowel of a spur; posterior gill-covers armed with a single spine: fins and tail marked across the rays by brown spotted streaks; native of Japan.

5. *Holocentrus surinamensis*, Surinam holocentrus: length twelve inches; habit of a carp; general colour brown, with several large, roundish, obscurely-yellow patches on each side; head and gill-covers red; mouth small; dorsal fin scaly at the base of the back-part; tail crossed near the base by a brown bar: native of Surinam, where it is highly esteemed for the table, being considered as one of the best fishes which the country produces.

6. *Holocentrus afer*, African holocentrus; length twelve inches; outline of the body, exclusive of the fins, somewhat resembling that of a sole; thickness considerable; scales very small, but those on the posterior gill-covers considerably larger than the rest; dorsal fin covered with small scales, and furnished on the fore-part with extremely thick or strong spines; back part and anal fin rounded, and reaching to within a little distance of the tail, which is remarkably small for the size of the fish, and of a round shape; pectoral fins, whitish; ventral, pale red; native of the coasts of Guinea, feeding on marine insects, &c. and in considerable estimation as a food.

HOLLY. See **ILEX**.

HOLLAND, in commerce, a fine and close kind of linen, so called from its being first manufactured in Holland.

HOLOSTEUM, a genus of the trigynia order, in the triandria class of plants, and in the natural method ranking under the 22d order, caryophyllei. The calyx is pentaphyllous; the petals five; the capsule, unilocular, and nearly cylindrical, opening at top. There are five species.

HOLOTHURIA, in zoology, a genus belonging to the order of vermes mollusca. The body, detached, naked, gibbous, terminated by the anus. Many tentacula at the other extremity surrounding the mouth. There are nine species, all inhabitants of the ocean. The following descriptions of three species are given by Mr. Barbut.

1. The tremula, or quivering holothuria, "commonly measures eight inches in length when dead; but alive it extends itself to more than a foot, or contracts its body into a ball. Its figure is cylindric, the diameter of which is every way equal to an inch and a few lines. The belly is of a pale brown, and set all over with cylindric tentacula, in such numbers that the head of a pin could scarcely find room between. By the help of these tentacula, the holothuria fixes its body at the bottom of the sea, so as not to be easily forced away by tempests, which would otherwise happen the more frequently, as this zoophyte dwells near the shores where the water scarcely rises to a fathom's height.

2. The physalis, or bladder-shaped holothuria. The body of this species is oval, approaching to triangular, of a glossy transparency; the back sharp-edged, of a dark green colour, whence run out a number of sinews; anteriorly the body is of a reddish hue. The trunk spiral, reddish towards the thicker end. Many tentacula of unequal length under that thicker end; the shorter ones are taper and thicker, the middle ones capillary, the point clay-colour, and in shape like a ball; the rest, which are longer, are filiform, of which the middlemost is thicker and twice as long. Brown, in his Jamaica, calls it a diaphanous bladder with numerous tentacula representing a man's belly; above it is furnished with a comb full of cells; under the other extremity hang a number of branchy tentacula. It inhabits the seas.

3. The pentactes, or five-rowed holothuria, has the mouth encompassed with tentacula, the body bearing tentacula five different ways. The animal is of a red colour, nearly oval, or somewhat cylindrical, assuming various shapes. The mouth is set round with ten rays, bristly at the points; the body is longitudinally dotted with warts. It inhabits the sea of Norway.

HOLY-GHOST, *order of the*, the principal military order in the old government of France, instituted by Henry III. in 1569.

HOLLOW-SQUARE, in the military art, a body of foot drawn up, with an empty space in the middle for colours, drums, and baggage.

HOLLOW-TOWER, according to Harris, is a rounding made of the remainder of two brisures, to join the curtain to the orillon, where the small shot are played, that they may not be so much exposed to the view of the enemy.

HOMAGE. In the original grants of lands and tenements by way of fee, the lord did not only tie his tenants to certain services, but also took a submission, with promise and oath to be true and loyal to him as their lord and benefactor. This submission was and is called homage.

HOMAGE ANCESTREL, is where a man's ancestors, time out of mind, held their land of their lord and his ancestors, by homage;

and if such lord has received homage, he is bound to acquit the tenant against all other lords above him of all service; and if the tenant has done homage to his lord, and is impleaded, and vouches the lord to warranty, the lord is bound to warrant him; and if the tenant loses, he shall recover in value against the lord so much of the lands as he had at the time of the voucher, or any time after.

HOMAGE JURY, a jury in a court baron, consisting of tenants that do homage to the lord of the fee, and there by the feudists are called pares curiæ; they inquire and make presentments of defaults and deaths of tenants, admittances, and surrenders in the lord's court, &c.

HOMALIUM, a genus of the class and order polyandria trigynia. The calyx is six or seven-parted: corolla, six or seven-petalled: stamina, 21 in three bodies: pericarpium, one-celled, many-seeded: There are two species, a tree of Jamaica and a shrub of Guiana.

HOMICIDE, properly so called, is the killing of a man by a man. Of this there are several species, as homicide by self-defence, homicide by misadventure, justifiable homicide, manslaughter, chance-medley, and murder.

Homicide by self-defence. Homicide se defendendo, or in a man's own defence, seems to be, where one has no other possible means of preserving his life from one who combats with him on a sudden quarrel, and kills the person by whom he is reduced to such inevitable necessity. 1 Haw. 75.

And not only he who on an assault retreats to a wall, or some such strait, beyond which he can go no farther before he kills the other, is judged by the law to act upon unavoidable necessity; but also he, who being assaulted in such a manner and in such a place, that he cannot go back without manifestly endangering his life, kills the other without retreating at all. Id.

And though a person who retreats from an assault to the wall should give the other wounds in his retreat, yet if he gives him no mortal wound till he gets thither, and then kills him, he is guilty of homicide se defendendo only. Id.

But if the mortal wound was given first, then it is manslaughter. Hale's Pl. 42.

Homicide by misadventure, is where a man in doing a lawful act without any intent of hurt, unfortunately chances to kill another, as where a labourer being at work with an hatchet, the head thereof flies off, and kills one who stands by. 1 Haw. 73.

It seems clear, that neither homicide by misadventure, nor homicide se defendendo are felonious, because they are not accompanied with a felonious intent, which is necessary in every felony. 1 Haw. 29.

Justifiable homicide. To make homicide justifiable, it must be owing to some unavoidable necessity, to which a person who kills another must be reduced, without any manner of fault in himself.

And there must be no malice coloured under pretence of necessity; for wherever a person who kills another, acts in truth upon malice, and takes occasion upon the appearance of necessity to execute his own private revenge, he is guilty of murder. 1 Haw. 69.

But if a woman kills him who assaults to

ravish her, it is no felony; or if a man comes to burn my house, and I go out thereof and kill him, it is no felony. Id. 39.

If any evil-disposed person shall attempt feloniously to rob or murder any person in any dwelling-house, or highway, or feloniously attempt to break any dwelling-house in the night time, and shall happen to be slain in such felonious attempt, the slayer shall be discharged, and shall forfeit no lands, nor goods. 24 H. VIII. c. 5.

Justifiable homicide of a public nature, is such as is occasioned by the due execution or advancement of public justice, with regard to which it must be observed.

1. That the judgment, by virtue whereof any person is put to death, must be given by one who has legal jurisdiction in the cause; for otherwise both judge and officer may be guilty of felony.

2. The execution must be pursuant to, and warranted by the judgment, otherwise it is without authority; and consequently, if a sheriff shall behead a man, when it is no part of the sentence to cut off the head, he is guilty of felony. 1 Haw. 70.

Manslaughter. Homicide against the life of another, is either with or without malice; that which is without malice is called manslaughter, or sometimes chance medley, by which is understood such killing as happens either on a sudden quarrel, or in the commission of an unlawful act, without any deliberate intention of doing any mischief at all. 3 Inst. 56.

Hence it follows, that there can be no accessaries to this offence before the fact, because it must be done without premeditation; but there may be accessaries after the fact. Id.

The only difference between murder and manslaughter, is, that murder is upon malice aforethought, and manslaughter upon a sudden occasion, as if two meet together, and striving for the wall the one kills the other, this is manslaughter and felony. And so it is if they had, on that sudden occasion, gone into the field and fought, and the one had killed the other, this had been but manslaughter and no murder, because all that followed was but a continuance of the first sudden occasion, and the blood was never cooled till the blow was given. 3 Inst. 55.

Chance or chance-medley. Authors of the first authority disagree about the application of this word; by some it is applied to homicide by misadventure, by others to manslaughter. The original meaning of the word seems to favour the former opinion, as it signifies a sudden or casual meddling or contention; but homicide by misadventure supposes no previous meddling or falling out.

Murder is the highest crime against the law of nature that a man is capable of committing.

Murder is when a man of sound memory, and at the age of discretion, unlawfully kills another person under the king's peace with malice aforethought, either expressed by the party, or implied by the law, so as the party wounded or hurt die of the wound or hurt within a year and a day. 3 Inst. 47.

And the whole day on which the hurt was done, shall be reckoned the first. 1 Haw. 79.

By malice expressed, is meant a deliberate intention of doing any bodily harm to another, whereunto by law a person is not authorized.

And the evidences of such malice must arise from external circumstances discovering that inward intention; as lying in wait, menacings antecedent, former grudges, deliberate compassings and the like, which are various, according to the variety of circumstances. 1 H. H. 451.

Malice implied, is where a person voluntarily kills another, without any provocation; for in this case the law presumes it to be malicious, and that he is a public enemy of mankind. 1 H. H. 455.

In general any formed design of doing mischief may be called malice; and therefore not such killing only as proceeds from premeditated hatred or revenge against the person killed, but also in many other cases, such as is accompanied with circumstances which shew the heart to be perversely wicked, is judged to be of malice prepense, or aforethought, and consequently murder. 2 Haw. 80.

If a man kills another, it shall be intended *prima facie* that he did it maliciously, unless he makes the contrary appear, by shewing that he did it on a sudden provocation or the like. 1 Haw. 82.

When the law makes use of the term malice aforethought, as descriptive of the crime of murder, it must not be understood in that narrow restrained sense, to which the modern use of the word malice is apt to lead one, a principle of malevolence to particulars; for the law by the term malice, in this instance, means, that the fact has been attended with such circumstances as are the ordinary symptoms of a wicked heart, regardless of social duty, and fatally bent upon mischief. Fost. 256.

The law so far abhors all duelling in cold blood, that not only the principal who actually kills the other, but also his seconds are guilty of murder, whether they fought or not; and it is holden that the seconds of the person killed are also equally guilty, in respect to that countenance which they give to their principals in the execution of their purpose, by accompanying them therein, and being ready to bear a part with them. 1 Haw. 82.

Also it seems agreed, that no breach of a man's word or promise, no trespass either to land or goods, no affront by bare words or gestures, however false or malicious it may be, and aggravated with the most provoking circumstances, will excuse him from being guilty of murder who is so far transported thereby, as immediately to attack the person who offends, in such a manner as manifestly endangers his life, without giving him time to put himself upon his guard, if he kills him in pursuance of such assault, whether the person slain did at all fight in his defence or not. Id.

HOMINE REPLEGIANDO, in law, is an antient writ that lies for bailing a person out of prison, where any one is confined without commandment of the king or his judges; or for any cause that is repleviable. This writ is directed to the sheriff, commanding him to replevy the prisoner. In case a person takes away secretly, or keeps in his custody any

person against his will, on oath made thereof, and a petition to the lord chancellor, he will grant a writ of replegiari facias, upon which the sheriff returns an elongatus, and then there issues a *capias* in withernam, to take the party so offending.

HOMOGENEOUS SURDS, those which have the same radical character, or signs, as $\sqrt[2]{a}$ and $\sqrt[2]{b}$.

HOMOLOGOUS, in geometry, an appellation given to the corresponding sides and angles of similar figures, as being proportional to each other.

HOMOLOGOUS THINGS, in logic, those which agree in name, but are of different natures.

HONEY, a saccharine substance prepared by the bees (see *APIS*). It has a white or yellowish colour, a soft and grained consistence, a saccharine and aromatic smell. By distillation it affords an acid phlegm and an oil, and its coal is light and spongy like that of the mucilage of plants. Nitric acid extracts from it oxalic acid precisely as it does from sugar; it is very soluble in water, with which it forms a syrup, and like sugar passes to the vinous fermentation. Mr. Cavezzali has proved lately that honey is composed of sugar, mucilage, and an acid. The sugar may be separated by melting the honey, adding carbonate of lime in powder as long as any effervescence appears, and scumming the solution while hot. The liquid thus treated gradually deposits crystals of sugar when allowed to remain in a glass vessel. There are three distinctions of honey, according to its purity, fluidity, and the manner in which it has been procured from the honeycombs. The first and finest kind is virgin-honey, or the first produce of a swarm, obtained from the combs without pressing; these being only set to drain, in order to its running out. The second kind is that known by the name of white-honey, being thicker than the former, and often indeed almost solid; it is procured by pressing the combs, but without the assistance of heat. The third and worst kind is the common yellow honey, obtained from the combs first heated over the fire, and then pressed.

HONEY-COMB, a waxen structure, full of cells, framed by the bees, to deposit their honey and eggs in.

The construction of the honey-comb seems one of the most surprising of the works of insects, and the materials of which it is composed, which, though evidently collected from the flowers of plants, yet do not, that we know of, exist in them in that state, has given great cause of speculation to the curious. The regular structure of the comb is also equally wonderful. When the several cells in it are examined, it should seem that the nicest rules of geometry had been consulted for its composition, and all the advantages that could be wished, or desired, in a thing of that kind, are evidently found in it. Each cell consists of six plane sides, which are all trapeziums, but equal to each other; the bottom of the cell is contrived with three rhombuses, *HKDI*, *DEFI*, and *FGHI*, (plate Miscel. fig. 124) so disposed as to constitute a solid angle at *I*, under the three equal angles *DIH*, *DIF*, and *HIF*, each of which is double the maximum angle of $54^{\circ} 44' = DIK = DKI$. Hence it comes to pass, that a less quantity of surface is suf-

ficient to contain a given quantity of honey, than if the bottom had been flat, in the proportion of 4658 to 5550, as has been found by calculation; that is, nearly a fifth of the whole, so far as the figure in the end of the cells extends, in each; which fifth part of wax and labour saved, amounts to a vast deal in the whole comb. The sides of the cells are all much thinner than the finest paper, and yet they are so strengthened by their disposition, that they are able to resist all the motions of the bee within them, as they are frequently obliged to be. The effect of their thrusting their bodies into the cells would be the bursting of those cells at the top, was not this well-guarded against. But to prevent this, the creatures extend a cord, or roll of wax, round the verge of every cell, in such a manner that it is scarcely possible they should split in that particular part. This cord or roll is at least three times as thick as the sides of the cell, and is even much thicker and stronger at the angles of the cells, than elsewhere, so that the aperture of each cell is not regularly hexagonal, though its inner cavity is perfectly so. See fig. 125.

The several combs are all placed parallel to one another (fig. 126) and there is such a space left between them, that the bees can easily pass; and often they place a part of the comb in a contrary direction to the rest, so that while the others are placed horizontally, these stand perpendicularly.

The celerity with which a swarm of bees received into a hive, where they find themselves lodged to their minds, bring their works of the combs to perfection is amazing. There are vast numbers at work all at once; and that they may not incommode one another, they do not work upon the first comb till it is finished, but when the foundation of that is laid, they go to work upon another, so that there are often the beginnings of three or four stories made at once, and so many parties allotted to the carrying on the work of each. In a very few days a new swarm will have completed several combs of the depth of four or five inches each.

HONEY-STONE. See *MELLITE*.

HONOUR, is used for a seignory or lordship, on which inferior lordships and manors depend; for as a manor consists of several lands, tenements, services, and customs, so an honour contains several manors, knights-fees, &c.

HONOUR-COURTS, are courts held within the honours or seignories.

HONOUR, *maids of*, are six young ladies in the household of the queen, and princess royal; the salary of those of a queen are 300*l.* each, and those of the princess dowager of Wales, 200*l.*

HONOUR-POINT, in heraldry, is that next above the centre of the escutcheon, dividing the upper part into two equal portions.

HOOF, the horny substance that covers the feet of divers animals, as oxen, horses, sheep, &c. See *HORN*.

HOOPING-COUGH. See *MEDICINE*.

HOP. See *HUMULUS*.

HOPEA, a genus of the polyandria order, in the polyadelphia class of plants. The calyx is quinquefid, superior; the corolla pentapetalous; the stamina are many, and coagulated into five pencils; there is one style; the

fruit is a plum, with a trilocular kernel. There is only one species, the tinctoria, a native of Carolina.

HORARY, or **HOURLY-CIRCLE**. See *Use of the GLOBE*.

HORARY CIRCLES, or **LINES**. See *Drilling*.

HORARY MOTION of the earth, the arch it describes in the space of an hour, which is nearly 15 degrees, though not accurately so, as the earth moves with different velocities, according to its greater or lesser distance from the sun.

HORDEUM, *barley*, a genus of the triandria-trigynia class of plants, the corolla whereof consists of two valves; the inferior valve is angular, of an ovato-acuminated figure, bellied, and longer than the cup, and terminates in a very long arista; the anterior valve is lanceolated, plane and smaller; the corolla serves as a pericarpium, surrounding the seed, and not letting it out; the seed is oblong, ventricose, pointed at each end, and marked with a longitudinal furrow. See *HUSBANDRY*.

HORIA, in entomology, a genus of the coleoptera order. Antennae moniliform; feelers four, thicker towards the tip; lip linear, rounded at the end. There are two species; the testacea, and the dermestoides.

HORIZON. See *ASTRONOMY* and *GEOGRAPHY*.

HORIZONTAL DIAL. See *DIALLING*.

HORIZONTAL LINE. See *PERSPECTIVE*.

HORIZONTAL PLANE, that which is parallel to the horizon of the place, or nothing inclined thereto. The business of levelling is to find whether two points are in the horizontal plane, or how much the deviation is.

HORIZONTAL RANGE of a piece of ordnance, is the distance at which it falls on or strikes the horizon, or on a horizontal plane, whatever is the angle of elevation or direction of the piece. When the piece is pointed parallel to the horizon, the range is then called the point-blank or point-blanc range.

The greatest horizontal range, in the parabolic theory, or in a vacuum, is that made with the piece elevated to 45 degrees, and is equal to double the height from which a heavy body must freely fall to acquire the velocity with which the shot is discharged. Thus, a shot being discharged with the velocity of v feet per second; because gravity generates the velocity $2g$ or $32\frac{1}{6}$ feet in the first second of time, by falling $16\frac{1}{2}$ or g feet, and because the spaces descended are as the squares of the velocities, therefore as $4g^2 : v^2 :: g : \frac{v^2}{4g}$, the space a body must descend to acquire the velocity v of the shot or the space due to the velocity v ; consequently the double of this, or $\frac{v^2}{2g} = \frac{v^2}{32\frac{1}{6}}$ is the greatest horizontal range with the velocity v , or at an elevation of 45 degrees; which is nearly half the square of a quarter of the velocity.

In other elevations, the horizontal range is as the sine of double the angle of elevation; so that, any other elevation being e , it will be, as radius $1 : \sin. 2e :: \frac{v^2}{32\frac{1}{6}} : \frac{v^2}{32\frac{1}{6}} \times \sin. 2e$, the range at the elevation e , with the velocity v .

But in a resisting medium, like the atmosphere, the actual ranges fall far short of the above theorems, inasmuch that with the great

velocities the actual or real ranges may be less than the tenth part of the potential ranges; so that some balls, which actually range but a mile or two, would in vacuo range 20 or 30 miles. And hence also it happens that the elevation of the piece, to shoot farthest in the resisting medium, is always below 45°, and gradually the more below it as the velocity is greater; so that the greater velocities with which balls are discharged from cannon with gunpowder, require an elevation of the gun equal to but about 30°, or even less. And the less the size of the balls is too, the less must this angle of elevation be to shoot the farthest with a given velocity. See *PROJECTILE* and *GUNNERY*.

HORN, *cornu*, in physiology, a hard substance growing on the heads of animals, particularly the cloven-footed quadrupeds; and serving them both as weapons of offence and defence.

Horns are not very hard, as they may be easily cut with a knife or rasped with a file; but they are so tough as not to be capable of being pounded in a mortar. When in thin plates, they have a degree of transparency, and have been sometimes substituted for glass in windows. When heated sufficiently, they become very soft and flexible, so that their shape may be altered considerably. Hence they may be gradually squeezed into a mould, and wrought into various forms, as is well known.

The quantity of earthy matter which they contain is exceedingly small. Mr. Hatchett burnt 500 grains of ox-horn. The residuum was only 1.5 grain, and not the half of this was phosphat of lime. Seventy-eight grains of the horn of the chamois left only 0.5 of residue, of which less than the half was phosphat of lime. They consist chiefly of a membranous substance, which possesses the properties of coagulated albumen; and probably they contain also a little gelatine. Hence we see the reason of the products that are obtained when these substances are subjected to distillation.

The horns of the hart and buck must, however, be excepted. From the experiments of Scheele and Rouelle, together with those of Hatchett, we know that these substances possess exactly the properties of bone, and are composed of the same constituents, excepting only that the proportion of cartilage is greater. They are intermediate, then, between bone and horn.

The nails, which cover the extremities of the fingers, are attached to the epidermis, and come off along with it. Mr. Hatchett has ascertained that they are composed chiefly of a membranous substance, which possesses the power of coagulated albumen. They seem to contain also a little phosphat of lime. Water softens, but does not dissolve them. But they are readily dissolved and decomposed by concentrated acids and alkalies. Hence it appears that nails agree with horns in their nature and composition. Under the head of nails must be comprehended the talons and claws of the inferior animals, and likewise their hoofs, which differ in no respect from horn.

The substance called tortoise-shell is very different from shells in its composition, and approaches much nearer to the nature of nail: for that reason we have placed it here. When long macerated in nitric acid, it softens, and

appears to be composed of membranes laid over each other, and possessing the properties of coagulated albumen. When burnt, 500 grains of it yield three of earthy matter, consisting of phosphat of lime and soda, with a little iron.

The scales of animals are of two kinds: some, as those of serpents and other amphibious animals, have a striking resemblance to horn; while those of fish bear a greater resemblance to mother-of-pearl. The composition of these two kinds of shells is very different.

The scales of fish, as has been observed by Lewenhoeck, are composed of different membranous laminae. When immersed for four or five hours in nitric acid, they become transparent, and perfectly membranaceous. The acid, when saturated with ammonia, gives a copious precipitate of phosphate of lime. Hence they are composed of alternate layers of membrane and phosphat of lime. To this structure they owe their brilliancy. Mr. Hatchett found the spicula of the shark's skin to be similar in its composition, but the skin itself yielded no phosphat of lime.

The horny scales of serpents, on the other hand, are composed alone of a horny membrane, and are destitute of phosphat of lime. They yield, when boiled, but slight traces of gelatine: the horn-like crusts which cover certain insects and other animals appear from Mr. Hatchett's experiments to be nearly similar in their composition and nature.

The casting of the horns of deer is a singular phenomenon, the true reason of which seems to be a stoppage of the circulation; so that being deprived of the nourishing juice, they fall off much in the same manner as the leaves of trees in autumn. About ten days after the horns are cast, the new ones begin to appear: these at first are soft and hairy, but they afterwards grow hard, and the creature rubs off the hair.

Horns make a considerable article in the arts and manufactures. Bullocks' horns, softened by the fire, serve to make lanthorns, combs, knives, ink-horns, tobacco-boxes, &c.

Dyeing of horns. Black is performed by steeping brass in aqua-fortis till it is turned green: with this the horn is to be washed once or twice, and then put into a warmed decoction of logwood and water. Green is begun by boiling it, &c. in alum-water, then with verdigris, ammoniac, and white-wine vinegar, keeping it hot therein till sufficiently green. Red is begun by boiling it in alum-water, and finished by decoction in a liquor compounded of quicklime steeped in rain-water, strained, and to every pint an ounce of Brazil wood added. In this decoction the bone, &c. is to be boiled till sufficiently red.

Dr. Lewis informs us, that horns receive a deep black stain from solution of silver. It ought to be diluted to such a degree as not sensibly to corrode the subject, and applied two or three times, if necessary, at considerable intervals, the matter being exposed as much as possible to the sun, to hasten the appearance and deepening of the colour.

Dyeing or staining horn to imitate tortoise-shell. The horn to be dyed must be first pressed into proper plates, scales, or other flat form, and the following mixture prepared: Take of quick-lime two parts, and

of litharge one part; temper them together to the consistence of a soft-paste with soap-ley. Put this paste over all the parts of the horn, except such as are proper to be left transparent, in order to give it a near resemblance of the tortoise-shell. The horn must remain in this manner covered with the paste till it is thoroughly dry; when, the paste being brushed off, the horn will be found partly opaque and partly transparent, in the manner of tortoise-shell, and when put over a foil of the kind of latten called assidue, will be scarcely distinguishable from it. It requires some degree of fancy and judgment to dispose of the paste in such a manner as to form a variety of transparent parts, of different magnitudes and figures, to look like the effect of nature; and it will be an improvement to add semitransparent parts, which may be done by mixing whiting with some of the paste to weaken its operation in particular places, by which spots of a reddish brown will be produced, which if properly interspersed, especially on the edges of the dark parts, will greatly increase both the beauty of the work and its similitude to real tortoise-shell.

HORN is also a musical instrument of the wind kind, chiefly used in hunting, to animate the hunters and the dogs, and to call the latter together. The French horn is bent into a circle, and goes two or three times round, growing gradually larger and wider towards the end, which in some horns is nine or ten inches over.

HORNS of insects, the slender oblong bodies projected from the heads of those animals, and otherwise called antennæ or feelers. See ENTOMOLOGY.

HORNBLLENDE. This mineral enters into the composition of many mountains. It is also amorphous, but frequently also crystallized. The primitive form of its crystals is a rhomboidal prism, the faces of which are inclined at angles of $124^{\circ} 34'$ and $55^{\circ} 26'$, and whose bases are angles of $122^{\circ} 56'$ and $57^{\circ} 4'$. The most common variety is a six-sided prism, terminated by trihedral or tetrahedral summits.

HORNBLLENDE, common. Its texture is very conspicuously foliated; fracture conchoidal; fragments often rhomboidal; opaque; tough; specific gravity 2.922 to 3.41; colour black, blackish-green, olive-green, or leek-green; streak greenish. It neither becomes electric by friction nor heat. Before the blow-pipe it melts into a black glass. A specimen of black hornblend, analysed by Mr. Hermann, was composed of

37 silica
27 alumina
25 iron
5 lime
3 magnesia

97

HORNBLLENDE, basaltic. This stone is found commonly in basaltic rocks; hence the name *basaltine*, which was imposed by Mr. Kirwan. It is crystallized either in rhomboidal prisms, or six or eight-sided prisms, terminated by three-sided pyramids. Its texture is foliated; its fracture uneven; specific gravity 3.333; colour black, dark-green, or yellowish-green; streak white; transmits a reddish-yellow light. Before the blow-pipe

it melts into a greyish-coloured enamel, with a tint of yellow. A specimen, seemingly of this stone, analysed by Bergman, contained

58 silica
27 alumina
9 iron
4 lime
1 magnesia

99

HORNBLLENDE, shistose. Colour greenish-black or deep green; forms strata; structure shistose; texture radiated or fibrous; opaque; brittle; streak greenish grey; moderately heavy; gives an argillaceous smell when breathed upon. This mineral is often confounded with slate. In Sweden it is employed for covering houses.

HORNERS, those artificers whose business it is to prepare various utensils of the horns of cattle. The horners were a very antient and considerable fraternity in the city of London some hundred years ago. In the reign of Edward II. they complained to parliament, that by foreigners buying up the horns in England, they were in danger of being ruined, and this business lost to the nation. For this reason was made the statute 6 Edw. IV. by which the sale of horns to foreigners (except such as the said horners refused) was prohibited; and the wardens had power granted them to search all the markets in London and 24 miles round, and to inspect Stourbridge and Ely fairs, to prevent such practices, and to purchase horns at stated prices. But on plausible pretences this law was repealed in the reign of James I. and thereupon the old evil revived. The horners again applied to parliament, and king Edward's statute was renewed (excepting as to the inspection of the fairs), and still remains in force. The importation of unwrought horns into this country is also prohibited. The present company of horners were incorporated January 12, 1638.

HORN-FISH, a species of esox, otherwise called gar-fish. See ESOX.

HORN-WORK, in fortification, an out-work composed of two demi-bastions, joined by a curtain. See FORTIFICATION.

HORNET, in zoology, a species of vespa with a black thorax, and double black spots on the segments of the body. See VESPA.

HORNSTONE, in mineralogy. This stone is usually amorphous, occurring sometimes in mass, and sometimes in round balls. Fracture splintery, and sometimes conchoidal; specific gravity 2.7; colour greyish-blue, but sometimes grey, red, blue, green, and brown, of different shades. According to Kirwan, it is composed of

72 silica
22 alumina
6 carbonat of lime

100

HORSE. See EQUUS.

HORSE-DEALERS. Every person exercising the trade or business of a horse-dealer, must take out a licence from the stamp-office, for which he shall pay annually, if within London, Westminster, the bills of mortality, the parish of St. Pancras, or the borough of Southwark, 20l.; elsewhere, 10l.

The commissioners are to grant licences to horse-dealers for not exceeding one year;

and every licence shall cease on September 29, then in the year for which the same shall be issued, and commence from the date; and every licence taken out for any year subsequent to the year in which the same shall be issued, shall commence from September 29, then next ensuing, and continue till September 29 following; and a fresh licence is to be taken out ten days at least before the expiration of the year.

One licence is sufficient for partners, and the licence is confined to the place mentioned therein. But no licences to be granted to horse-dealers, unless they declare they seek their living by buying and selling horses, and add the name of the place where the said business is carried on. 29 Geo. III. c. 49.

Horse-dealers so licenced, shall cause the words *licenced to deal in horses* to be painted or written in large and legible characters either on a sign hung out or on some visible place in the front of their house, gate-way, or stables; and if they shall sell any horse without fixing such token, they shall forfeit 10l. to be recovered by action, half to the king, and half to the informer. 36 Geo. III. c. 17.

Horse-dealers who shall, after January 1, 1796, carry on the said business without having obtained a licence under this act, shall be liable to be assessed the duties on riding-horses, and shall deliver lists thereof as other persons.

HORSE-SHOE, in fortification, is a small work, sometimes of a round and sometimes of an oval figure, inclosed with a parapet, sometimes raised in the moat or ditch, or in low grounds, and sometimes to cover a gate, or to serve as a lodgment for soldiers. See FORTIFICATION.

HORSE-SHOES. See FARRIERY.

HORSE, in a ship, is a rope made fast to each yard arm, and on which the men stand to furl the sails. It is also a wooden frame with a rowel fixed in it, made use of by the riggers to woad ships-masts.

HORSES. It shall be lawful for any person, native or foreigner, at any time to ship, lade, and transport by way of merchandize, horses into any parts beyond the seas in amity with his majesty, paying for each horse, mare, or gelding, 5s. and no more.

No person convicted for feloniously stealing a horse, gelding, or mare, shall have the privilege of clergy. 1 Edw. VI. c. 12. And not only all accessories before such felony done, but also all accessories after such felony, shall be deprived and put from all benefit of their clergy, as the principal, by statute heretofore made, is or ought to be.

If a horse be stolen out of the stable, or other curtilage of a dwelling-house, in the night time, it falls under the denomination of burglary; if in the day-time, it falls under the denomination of larceny from the house; and in either case there is a reward of 40l. for convicting an offender, and the prosecutor is entitled to a certificate which will exempt him from all parish and ward offices in the parish and ward where the burglary or larceny is committed, and which may be once assigned over, and will give the same exemption to the assignee as to the original proprietor. Burn's Just. 621.

If an unsound horse is sold at the price of a sound horse, though not absolutely war-

ranted to be sound, the seller sins against the law of morality and the law of the land; but if he acknowledges him not to be sound, and sells him greatly under the value of a sound horse, as if he disposes of him for 25*l.* when he would have been worth 50*l.* if sound, such sale may be considered as fair and legal.

If a horse which is warranted sound at the time of sale is proved to have been at that time unsound, it is not necessary that he should be returned to the seller. No lapse of time elapsed after the sale will alter the nature of a contract originally false. Neither is notice necessary to be given; though the not giving notice will be a strong presumption against the buyer, that the horse at the time of sale had not the defect complained of, and will make the proof on his part much more difficult. The bargain is compleat; and if it is fraudulent on the part of the seller, he will be liable to the buyer in damages, without either a return or notice.

If on account of a horse warranted sound, the buyer shall sell him again at a loss, an action might *perhaps* be maintained against the original seller, to recover the difference of the price. 1 Hen. Black. 17.

Slaughtering horses. Great abuses having arisen, and many horses having been stolen, from the facility and safety of disposing of them to those who kept slaughter-houses for horses, some regulations and restrictions seemed absolutely necessary. It was no uncommon thing for horses of great value to be sold for the purpose of making food for dogs; the thief rather choosing to receive 20*s.* for a stolen horse, without fear or danger of detection, than venture to dispose of him publicly, though he might possibly have found a purchaser who would have given as many pounds for him. These considerations induced the legislature to pass the act of 26 Geo. III. c. 71, for regulating these slaughter-houses.

Killing or maiming horses. Where any person shall in the night-time maliciously, unlawfully, and willingly kill or destroy any horses, sheep, or other cattle, of any person, every such offence shall be adjudged felony, and the offender shall suffer as in the case of felony. 22 and 23 Car. II. c. 7.

Offenders may be transported for seven years, either at the assizes or at the sessions, by three justices of the peace, one to be of the quorum.

By the 9th Geo. I. c. 22. commonly called the black-act, it is enacted, that if any person shall unlawfully and maliciously kill, maim, or wound any cattle, every person so offending, being thereof lawfully convicted in any county of England, shall be adjudged guilty of felony, and shall suffer death, as in cases of felony, without benefit of clergy. But not to work corruption of blood, loss of dower, nor forfeiture of lands or goods.

Prosecution upon this statute shall or may be commenced within three years from the time of the offence committed, but not after.

If an horse or other goods are delivered to an inn-keeper or his servants, he is bound to keep them safely, and restore them when his guest leaves the house. 2 Black. 451.

If an horse is delivered to an agisting farmer, for the purpose of depasturing in his meadows, he is answerable for the loss of the horse, if it is occasioned by the ordinary ne-

glect of himself or his servants. Jones on Bailm. 91.

If a man rides to an inn, where his horse has eaten, the host may detain the horse till he is satisfied for the eating, and without making any demand. 14 Vin. Abr. 437. But an horse committed to an inn-keeper can only be detained for his own meat, and not for that of his guest or any other horse; for the chattels in such case are only in the custody of the law for the debt which arises from the thing itself, and not for any other debt due from the same party. 2 Rol. Abr. 85.

By the custom of London and Exeter, if a man commits an horse to an inn-keeper, if he eats out his price, the inn-keeper may take him as his own, upon the reasonable appraisement of four of his neighbours; which was it seems a custom arising from the abundance of traffic with strangers, that could not be known so as to be charged with an action. But it has been holden, though an inn-keeper in London may, after long keeping, have the horse appraised and sell him, yet, when he has in such case had him appraised, he cannot justify the taking him to himself at the price he was appraised at. Vin. Abr. 233.

HORTUS SICCUS, a *dry garden*, an appellation given to a collection of specimens of plants, carefully dried and preserved. The value of such a collection is very evident, since a thousand minutiae may be preserved in the well-dried specimens of plants, which the most accurate engraver would have omitted.

Among the different methods adopted by botanists for obtaining a hortus siccus, the following appear to be the most practicable:

1. Lay the plants flat between papers; then place them between two smooth plates of iron screwed together at the corners: in this state they are to be committed to a baker's oven for two hours. After being taken out, they must be rubbed over with a mixture consisting of equal parts of brandy and vinegar, then pasted down on paper with a solution of gum-tragacanth in water, after which they are to be laid in a book, where they will adhere, and retain their original freshness. The following method is however more simple:

2. Flatten the plant by passing a common smoothing-iron over the papers between which it is placed, and dry it slowly in a sand-heat. For this purpose the cold sand ought to be spread evenly, the smoothened plant laid gently on it, and sand sifted over so as to form a thick bed; the fire is then to be kindled, and the whole process carefully watched, till the plant is gradually and perfectly dried. Thus the colour of the tenderest herb may be preserved, and the most delicate flowers retain all their pristine beauty.

3. Another and far more complete method was suggested by the ingenious Mr. Whately. He directs those who intend to follow his plan, previously to procure—1. A strong oak-box of the same size and shape as those employed for packing up tin plates; 2. a quantity of fine sifted sand, sufficient to fill the box; 3. a considerable number of pieces of plant paper, from one to four inches square; and 4. some small flat leaden weights, and a few small bound books.

The plant is first to be cleared from the soil as well as the decayed leaves, and then laid on the inside of one of the leaves of a

sheet of common cap-paper. The upper leaves and flowers are next to be covered, when expanded, by pieces of the prepared paper, and one or two of the leaden weights placed on them. The remainder of the plant is now to be treated in a similar manner.

The weights ought next to be gently removed, and the other leaf of the sheet of paper folded over the opposite one, so as to contain the loose pieces of paper and plants between them. A book or two is now to be applied to the outside of the paper till the intended number of plants is thus prepared; when a box is to be filled with sand to the depth of an inch, one of the plants put in, and covered with sand sufficient to prevent the form of the plant from varying. The other plants may then be placed in succession, and likewise covered with a layer of sand, one inch thick between each; after which the whole is to be gently pressed down in a greater or less degree, according to the tenderness or firmness of the plants.

The box is next to be carefully placed before a fire, one side being occasionally a little raised, as may be most convenient; the sides being alternately presented to the fire two or three times in the day, or the whole may be put into an oven gently heated. In the course of two or three days the plants will be perfectly dry, when the sand ought to be taken out and put into another box: the plants should likewise be removed to a sheet of writing paper.

HOSPITALERS, an order of religious knights, now known by the title of knights of Malta.

HOT-BEDS, in gardening, beds made with fresh horse-dung, or tanner's bark, and covered with glasses to defend them from cold winds.

According to the quantity and quality of the materials put together for hot-beds, the heat will be proportioned as to strength and duration; and by a judicious use in making, and the management afterwards, many advantages may be obtained from them. The great point is, to suit the degree of heat to the nature of the different plants to be cultivated, that they may have neither more nor less than is necessary to promote a regular vegetation.

Two errors are common in the use of hot-beds, sowing or placing in the same bed things of a very different nature, as to the climate they grow best in, and forcing with too much heat even the tenderest. Though it may not answer our often too hasty views, the heat of a bed had better be slack than otherwise. A strong hot-bed that ought at least to be made a fortnight before it is used, is sometimes furnished by impatience in a few days, and various ill consequences follow, which naturally frustrate expectation.

The place where hot-beds are worked should be open to the full sun, catching it as early as possible in the morning, and having it as long as can be in the evening; and if not naturally sheltered, it should be screened from the north and north-east winds by a boarded fence or rather one of reeds, as from a solid fence the wind reverberates; but straw or flake-hurdles set endwise may do. A screen of some sort (and a close-clipt hedge is as good as any) not only protects the inclosure from the harsher winds, and confines the warm air, but keeps a rather un-

sightly work from view, and straws from blowing about, the litter of which is so disagreeable.

Working of the dung is necessary previous to the making of a hot-bed, *i. e.* it should be thrown together on an heap, in a conical form; and when it has taken a thorough heat, and has been smoking or sweating for two or three days, it should be turned over, moving the outside in, or mixing the colder parts with the hot. When it has taken heat again for two or three days, give it a second turn as before, and having lain the same time, it will be in proper order for making a good lasting bed with a steady heat. If in haste, it may be made into a bed after the first heating; but it will be better for shifting again, or even a third time. When dung is ready before wanted, keep turning it over, lest it should be too much spent. It will be proper to begin to work fresh dung a week or ten days before it is to be used; but if the dung is not fresh, it is only necessary to throw it together for once heating.

The size of a hot-bed, as to length and breadth, is of course to be according to the frame; and the height of it according to the season and the degree of heat requisite to the nature of the plant to be cultivated. In a dry soil, a bed may be sunk in the ground from six inches to a foot, to make it more convenient to get at and manage. But beds made forward in the season should rather be on the surface, for the sake of being able to add stronger linings, &c.

In case of an insufficient quantity of good horse-dung, that of cows, oxen, or pigs, if it is strawy, and not too wet, may be mixed with it, in the proportion of one-fourth or more, especially in an advanced part of the season, or to cultivate things that are only forcing, and do not naturally require heat.

When the season is pretty much advanced, hot-beds may be made of grass mowings (as from an orchard) and weeds, which is a common practice in the cyder countries. These heats, however, are often too violent, and last not long; yet they may be lined with the same materials if done in time, otherwise if a green hot-bed gets greatly cool, it will not be recovered. A grass bed may be used as soon as warm, but let it not be overweighted by putting on heavy frames, or more mould than necessary. It should rather be worked with hand-glasses or oiled paper covers.

Hot-beds are sometimes made of the refuse bark of a tanner's yard, and also of oak-leaves; but these must have walled pits for them of a large size, and are seldom used but in hot-houses. A bark-bed properly made, and managed by forking up at two or three month's end, &c. will hold a fair, moderate, and steady heat four, five, or six months.

To decrease the heat of a bed, several holes may be made in it, by thrusting an iron bar, or a thick smooth sharp-pointed stake, up to the middle, which holes are to be close stopt again with dung or hay when the heat is sufficiently abated.

The uses to which hot-beds may be applied are various, but chiefly for the cultivation of cucumbers and melons. At the spring of the year, hot-beds are commonly made use of for forcing crops of several vegetables, as radishes, carrots, cauliflowers, lettuces, potatoes, turneps, kidney-beans, purslane, tarragon, small sallading, &c. Fruits of several

sorts, as cherries, strawberries, raspberries, &c. are sometimes brought forward by dung heat; as also various shrubs and flowers, by means of forcing-frames. Tender annuals, as balsams and other flowers that necessarily require heat to bring them up, and the less tender, and some even of the hardy sorts, are also cultivated on hot-beds, or by other assistance from dung, to produce an earlier blow than could otherwise be had.

HOT-HOUSE, in salt-making, the place where they dry the salt, when taken out of the boiling-pan. It is situated near the furnace, which, by means of funnels or tubes, conveys the heat into it.

HOT-HOUSE, in gardening, an erection intended for the culture of the tender exotics of tropical climates. It is usually built lower than a greenhouse, with double flues, and a pit in the middle for tanner's bark, in which, as in a kind of hot-bed, the pots containing the plants are to be plunged. A hot-house should be kept at a regular heat, seldom less than 70°; and when the weather becomes about 10° below that extremity, the fires may be left off. The tan should be renewed twice a year, in spring and autumn; and care must be taken not to plunge the plants in it till the heat is risen to a proper degree.

The ingenious Dr. Anderson, so well known for his labours in agriculture, has lately constructed a hot-house to be kept warm by air chiefly warmed by the heat of the sun. It is entirely of glass, and the upper part is a close chamber to contain the heated air, which is let into the house by a valve. In the winter the chamber is heated by a lamp, and the warm air is admitted in the same manner as that which is warmed by the sun. The house is also moveable; but for further details we must refer to the doctor's *Agricultural Recreations*.

HOTCH-POT, in law, is used for mixing of lands given in marriage with other lands in fee which fall by descent; as where a man possessed of thirty acres of land has issue only two daughters, and after his having given with one of them ten acres in marriage, he dies possessed of the other twenty. Here she that is thus married, in order to gain her share of the rest of the land, must put her part given in marriage in hotch-pot; that is, she must refuse to take the sole profits of her lands, and cause it to be mingled with the other, so that an equal division may be made of the whole between her and her sister; by which means, instead of only her ten acres, she has fifteen.

HOVENIA, a genus of the class and order pentandria monogynia. The petals are five, convoluted; stigma trifid; capsule three-celled, three-valved. There is one species, a shrub of Japan.

HOVERING. Ships of 50 tons, laden with customable or prohibited goods, hovering on the coasts of this kingdom, within the limits of any port (and not proceeding from foreign parts), may be entered by officers of the customs, who are to take an account of the lading, and to demand and take a security from the master, by his bond to his majesty, in such sum of money as shall be treble the value of such foreign goods then on board; that such ship shall proceed (as soon as wind and weather and the condition of the ship will permit) on her voyage to foreign parts, and shall land the goods in some fo-

reign port; the master refusing to enter into such bond on demand, or who having given bond, shall not proceed on such voyage (unless otherwise suffered to make a longer stay by the collector or other principal officer of such port where the vessel shall be, not exceeding 20 days); in either of the said cases, all the foreign goods on board may be taken out by the customhouse-officers, by direction of the collector, and properly secured; and if they are customable, the duties shall be paid; and if prohibited, they shall be forfeited.

The officers of the customs may prosecute the same, as also the ship, if liable to condemnation. 3 Geo. III. c. 21.

Commanders of men of war, and customhouse-officers, may compel ships of 50 tons, or under, hovering within two leagues of shore, to come into port. 6 Geo. I. c. 21.

If any ship or vessel shall be found at anchor, or hovering within eight leagues of the coast (except between the North Foreland and Beachy Head), unless by distress of weather, having on board foreign spirits, in any vessel or cask which shall not contain 60 gallons at least, or any wine in casks (provided such vessel have wine on board), shall not exceed 60 tons burthen, or six pounds weight of tea, or 20 pounds weight of coffee, or any goods whatever liable to forfeiture upon importation, that such goods, with the ship and furniture, shall be forfeited; spirits for the use of seamen, not exceeding two gallons per man, excepted. 42 Geo. III. c. 82.

HOUND. See **CANIS**.

HOUR, *hora*, in chronology, an aliquot part of a natural day, usually a 24th, sometimes a 12th. See **ASTRONOMY**, **GEOGRAPHY**, &c.

There are different hours used by chronologers, astronomers, dialists, &c. Sometimes hours are divided into equal and unequal. Equal hours are the 24th part of a day and night precisely, that is, the time wherein 15 degrees of the equator mount above the horizon. These are also called equinoctial hours, because they are measured on the equinoctial; and astronomical, because used by astronomers. They are also differently denominated according to the manner of accounting them in different countries. Astronomical hours are equal hours, reckoned from noon or mid-day, in a continued series of twenty-four. Babylonish hours are equal hours reckoned in the same manner from sun-rise. The Italian hours are also equal hours, reckoned in the same manner too, from sun-setting. European hours are also equal hours, reckoned from midnight; 12 from thence to noon, and 12 more from noon to midnight. Jewish, or planetary, or antient hours, are the twelfth part of the artificial day and night, each being divided into 12 equal parts. Hence, as it is only in the time of the equinoxes that the artificial day is equal to the night, it is then only that the hours of the day are equal to those of the night. At other times they will be always either increasing or decreasing: and they will be the more or less unequal according to the obliquity of the sphere.

HOUSE. Every man's house is as his castle, as well to defend him against injuries, as for his repose.

Upon recovery in any real action or ejectment, the sheriff may break the house and

deliver seisin, &c. to the plaintiff, the writ being habere facias seisinam, or possessionem; and after judgment it is not the house of the defendant in right and judgment of the law.

In all cases where the king is party, the sheriff, if no door is open, may break the party's house to take him, or to execute other process of the king, if he cannot otherwise enter; but he ought first to signify the cause of his coming, and request the door to be opened: and this appears by the statute Westm. 1, 17, which is only in affirmance of the common law; and without default in the owner, the law will not suffer an house to be broken.

In all cases where the door is open, the sheriff may enter and make execution at the suit of any subject, either of body or goods; but otherwise where the door is shut, there he cannot break it to execute process at the suit of a subject.

Though an house is a castle for the owner himself and his family, and his own goods, &c. yet it is no protection for a stranger flying thither, or the goods of such a one, to prevent lawful execution; and therefore in such case, after request to enter, and denial, the sheriff may break the house. 5 Rep. 91.

If a person authorized to arrest another who is sheltered in an house, is denied quietly to enter into it, in order to take him, it seems generally to be agreed, that he may justify the breaking open of the doors upon a *capias* from the king's bench or chancery, to compel a man to find sureties for the peace or good behaviour, or even upon a warrant from a justice of the peace for such person.

So where one known to have committed treason, is pursued either with or without a warrant, by a constable or private person.

So where an affray is made in an house in the view or hearing of a constable; or where those who have made an affray in his presence fly to an house, and are immediately pursued by him, and he is not suffered to enter in order to suppress the affray in the first case, or to apprehend the affrayers in either case. 2 Haw. 86, 87.

A man ought so to use his house as not to damnify his neighbour: and a man may compel another to repair his house in several cases by the writ *de domo reparanda*. 1 Salk. 360.

If a man builds his house so close to mine, that his roof overhangs my roof, and throws the water of his roof upon mine, this is a nuisance for which an action will lie.

But depriving one of a mere matter of pleasure, as of a fine prospect, by building a wall or the like; this, as it abridges nothing really convenient or necessary, is no injury to the sufferer, and is therefore not an actionable nuisance. 3 Black. 217.

HOUSEHOLD, the whole of a family considered collectively, including the mistress, children, and servants: but the household of a sovereign prince includes only the officers and domestics belonging to his palace.

The principal officers of his majesty's household are, the lord steward, lord chamberlain of the household, the groom of the stole, the master of the great wardrobe, and the master of the horse. The civil government of the king's house is under the care of the lord steward of the king's household, who, as he is the chief officer, all his commands

are observed and obeyed. His authority extends over all the other officers and servants, except those of his majesty's chapel, chamber, and stable; and he is the judge of all crimes committed either within the court or the verge. Under him are the treasurer of the household, the comptroller, cofferer, the master of the household, the clerks of the green-cloth, and the officers and servants belonging to the accounting-house, the marshalsea, the verge, the king's kitchen, the household kitchen, the acatery, bakehouse, pantry, buttery, cellar, pastry, &c. Next to the lord steward is the lord chamberlain of the household, who has under him the vice-chamberlain, the treasurer, and comptroller of the chamber; 48 gentlemen of the privy chamber, 12 of whom wait quarterly, and two of them lie every night in the privy chamber; the gentleman usher, the grooms of the great chamber, the pages of the presence chamber; the mace-bearers, cup-bearers, carvers, musicians, &c.

The groom of the stole has under him the eleven other lords of the bed chamber, who wait weekly in the bed chamber, and by turns lie there a-nights on a pallet-bed; and also the grooms of the bed-chamber, the pages of the bed chamber and back stairs, &c.

The master or keeper of the great wardrobe has under him a deputy, comptroller, clerk of the robes, brusher, &c. and a number of tradesmen and artificers, who are all sworn servants to the king.

The master of the horse has under his command the e.uerries, pages, footmen, grooms, coachmen, farriers, saddlers, and all the other officers and tradesmen employed in his majesty's stables.

Next to the civil list of the king's court is the military, consisting of the band of gentlemen pensioners, the yeomen of the guard, and the troops of the household; of which the two first guard the king above stairs.

When the king dines in public, he is waited upon at table by his majesty's cup-bearers, carvers, and gentlemen sewers, the musicians playing all the time. The dinner is brought up by the yeomen of the guard, and the gentlemen sewers set the dishes in order. The carvers cut for the king, and the cup-bearers serve him the drink with one knee on the ground, after he has first tasted it in the cover.

HOUSTONIA, a genus of the monogynia order, in the tetrandria class of plants, and in the natural method ranking under the 47th order, stellate. The corolla is monopetalous and funnel-shaped; the capsule bilocular, dispermous, superior. There are two species, shrubs of America.

HOUTTYNIA, a genus of the class and order polyandria polygynia. The calyx is four-leaved; corolla none; stamina mixed with the pistils, seven about each gem. There is one species, an herb of the East Indies, having the habit of a polygonum.

HUDSONIA, a genus of the monogynia order, in the dodecandria class of plants. There is no corolla; the calyx is pentaphyllous and tubular; there are 15 stamina; the capsule is unilocular, trivalvular, and trispermous. There is one species, a shrub of Virginia.

HUE AND CRY, is the antient common

law process after felons, and such as have dangerously wounded any person, or assaulted any one with intent to rob him; and it has received great countenance and authority by several acts of parliament. In any of which cases, the party grieved, or any other, may resort to the constable of the vill; and, 1, give him such reasonable assurances thereof as the nature of the case will bear: 2. if he knows the name of him that did it, he must tell the constable the same: 3. if he knows it not, but can describe him, he must describe him, his person, or his habit, or his house, or such circumstances as he knows, which may conduce to the discovery: 4. if the thing is done in the night, so that he knows none of these circumstances, he must mention the number of persons, or the way they took: 5. if none of all these can be discovered, as where a robbery, or burglary, or other felony, is committed in the night, yet they are to acquaint the constable with the fact, and desire him to search his town for suspected persons, and to make hue and cry after such as may probably be suspected, as being persons vagrant in the same night; for many circumstances may happen to be useful for discovering a malefactor, which cannot at first be found out.

For the levying of hue and cry, although it is a good course to have a justice's warrant, where time will permit, in order to prevent causeless hue and cry; yet it is not necessary nor always convenient, for the felon may escape before the warrant is obtained. And upon hue and cry levied against any person, or where any hue and cry comes to a constable, whether the person is certain or uncertain, the constable may search suspected places within his vill, for the apprehending of the felon. And if the person against whom the hue and cry is raised, is not found in the constablewick, then the constable, and also every officer to whom the hue and cry shall afterwards come, ought to give notice to every town round about him, and to one next town only; and so from one constable to another, until the offender is found, or till they come to the sea-side. And this was the law before the conquest.

And in such cases it is needful to give notice in writing to the pursuers of the thing stolen, and of the colour and marks thereof, as also to describe the person of the felon, his apparel, horse, or the like, and which way he is gone, if it may be: but if the person that did the fact is neither known nor describable by his person, cloaths, or the like, yet such an hue and cry is good, and must be pursued, though no person certain can be named or described. 2 H. H. 100. 103.

HUER, a name given to certain fountains in Iceland, of a most extraordinary nature, forming at times jets d'eau of scalding water 94 feet high and 30 in diameter. They arise out of cylindrical tubes of unknown depths. Near the surface they expand into apertures of a funnel shape, and the mouths spread into a large extent of stalactical matter, formed of successive scaly concentric undulations. The playing of these stupendous spouts is foretold by noises roaring like the cataract of Niagara. The cylinder begins to fill: it rises gradually to the surface, and as gradually increases its height, smoking amazingly, and flinging up great stones. After attaining its greatest height, is gradually sinks till it totally disap-

pears. Boiling jets d'eaux and boiling springs are frequent in most parts of the island; and in many parts they are commonly applied to the culinary uses of the natives. The most capital is that which is called geyser or geyser, in a plain rising into small hills, and in the midst of an amphitheatre, bounded by the most magnificent and various-shaped icy mountains, among which the three-headed Hecla soars pre-eminent. These huers are not confined to the land; they rise in the very sea, and form scalding fountains amidst the waves. Their distance from the land is unknown; but the new volcanic isle, twelve miles off the point of Reickness, emitting fire and smoke, proves that the subterraneous fires and waters extend to that space; for those awful effects arise from the united fury of these two elements.

HUGONIA, a genus of the decandria order, in the monadelphia class of plants, and in the natural method ranking with those of which the order is doubtful. The corolla is pentapetalous; the fruit is a plum with a striated kernel. There is one species, a tree of the East Indies.

HUGUENOTS, a name given by way of contempt to the protestants of France. The name had its rise in the year 1560; but authors are not agreed as to its origin. The most plausible opinion, however, is that of Pasquier, who observes, that at Tours, the place where they were first thus denominated, the people had a notion that an apparition or hobgoblin, called king Hugon, strolled about the streets in the night-time; whence as those of the reformed religion met chiefly in the night to pray, &c. they called them Huguenots, that is, the disciples of king Hugon.

HULL, in the sea language, is the main body of a ship, without either masts, yards, sails, or rigging. Thus to strike a hull in a storm is to take in her sails, and to lash the helm on the lee-side of the ship; and to hull or lie a hull, is said of a ship whose sails are thus taken in, and helm lashed a-lee.

HUMERUS. See **ANATOMY**.

HUMERUS, *luxation of the*. See **SURGERY**.

HUMMING-BIRD. See **TROCHILUS**.

HUMULUS, *the hop*, a genus of the pentandria order, in the diœcia class of plants, and in the natural method ranking under the 53d order, scabridæ. The male calyx is pentaphyllous; there is no corolla: the female calyx is monophyllous, patent obliquely, and entire; there is no corolla, but two styles, and one seed within the calyx, the latter consisting of one large leaf. There is only one species, viz. the lupulus, which is sometimes found wild in hedges near houses and gardens, but probably is not indigenous. The stalk is weak and climbing; it creeps up the support in a spiral, ascending always from the right hand to the left.

Hops are said to have been first brought into England from the Netherlands in the year 1524. They are first mentioned in the English statute-book in the year 1552, viz. in the 5th and 6th Edw. VI. cap. 5.: and by an act of parliament of the first year of king James I. anno 1603, cap. 18. it appears that hops were then produced in abundance in England. The hop being a plant of great importance in this country, we shall consider

what relates to the culture and management of it under distinct heads.

Of soil. As for the choice of soil, the hop-planters esteem the richest and strongest ground the most proper; and if it is rocky within two or three feet of the surface, the hops will prosper well; but they will by no means thrive on a stiff clay or spongy wet land.

The Kentish planters account new land best for hops; they plant their hop gardens with apple-trees at a large distance, and with cherry-trees between; and when the land has done its best for hops, which they reckon it will in about ten years, the trees may begin to bear.

To plant hops. In the winter time provide your soil and manure for the hop-ground against the following spring. If the dung is rotten, mix it with two or three parts of common earth, and let it incorporate together till you have occasion to make use of it in making your hop-hills; but if it is new dung, then let it be mixed as before till the spring in the next year, for new dung is very injurious to hops.

Hops require to be planted in a situation so open as that the air may freely pass round and between them, to dry up and dissipate the moisture, whereby they will not be so subject to fire-blasts, which often destroy the middles of large plantations, while the out-sides remain unhurt.

The hills should be eight or nine feet asunder, that the air may freely pass between them. If the ground is intended to be ploughed with horses between the hills, it will be best to plant them in squares checquerwise; but if the ground is so small that it may be done with the breast-plough or spade, the holes should be ranged in a quincunx form. Which way soever you make use of, a stake should be stuck down at all the places where the hills are to be made.

Persons ought to be very curious in the choice of the plants as to the kind of hop; for if the hop-garden is planted with a mixture of several sorts of hops that ripen at several times, it will cause a great deal of trouble, and be a great detriment to the owner. The two best sorts are the white and the grey bind; the latter is a large square hop, more hardy, and is the more plentiful bearer, and ripens later than the former. There is another sort of the white bind, which ripens a week or ten days before the common; but this is tenderer, and a less plentiful bearer; but it has this advantage, that it comes first to market.

If there is a sort of hop you value, and would increase plants and sets from, the superfluous binds may be laid down when the hops are tied, cutting off the tops, and burying them in the hill; or when the hops are dressed, all the cuttings may be saved; for almost every part will grow, and become a good set the next spring.

As to the seasons of planting hops, the Kentish planters approve the months of October and March. The most usual time, however, of procuring them is in March, when the hops are cut and dressed.

As to the manner of planting the sets, there should be five good sets planted in every hill, one in the middle, and the rest round about sloping. Let them be pressed close with the hand, and covered with fine earth, and a

stick should be placed on each side the hill to secure it.

Dressing. As to the dressing of the hops, when the hop-ground is dug in January or February, the earth about the hills, and very near them, ought to be taken away with a spade, that you may come the more conveniently at the stock to cut it. About the end of February, if the hops were planted the spring before, or if the ground is weak, they ought to be dressed in dry weather; but else, if the ground is strong and in perfection, the middle of March will be a good time; and the latter end of March, if it is apt to produce over-rank binds, or the beginning of April may be soon enough. Then having with an iron picker cleared away all the earth out of the hills, so as to clear the stock to the principal roots, with a sharp knife you must cut off all the shoots which grew up with the binds the last year; and also all the young suckers, that none be left to run in the alley, and weaken the hill. It will be proper to cut one part of the stock lower than the other, and also to cut that part low that was left highest the preceding year. In dressing those hops that have been planted the year before, you ought to cut off both the dead tops and the young suckers which have sprung up from the sets, and also to cover the stocks with fine earth a finger's length in thickness.

The poling. About the middle of April the hops are to be poled, when the shoots begin to sprout up; the poles must be set to the hills deep into the ground, with a square iron picker or crow, that they may the better endure the winds; three poles are sufficient for one hill. These should be placed as near the hill as may be, with their bending tops turned outwards from the hill to prevent the binds from entangling; and a space between two poles ought to be left open to the south to admit the sun-beams.

The tying. As to the tying of hops, the buds that do not clasp of themselves to the nearest pole when they are grown to three or four feet high, must be guided to it by the hand, turning them to the sun, whose course they will always follow. They must be bound with withered rushes, but not so close as to hinder them from climbing up the pole. This you must continue to do till all the poles are furnished with binds, of which two or three are enough for a pole; and all the sprouts and binds that you have no occasion for, are to be plucked up; but if the ground is young, then none of these useless binds should be plucked up, but should be wrapped up together in the middle of the hill.

Gathering. About the beginning of July hops begin to blow, and will be ready to gather about Bartholomew-tide. A judgment may be made of their ripeness by their strong scent, their hardness, and the brownish colour of their seed. When by these tokens they appear to be ripe, they must be picked with all the expedition possible; for if at this time a storm of wind should come, it would do them great damage by breaking the branches, and bruising and discolouring the hops; and it is very well known that hops, being picked green and bright, will sell for a third more than those which are discoloured and brown.

The most convenient way of picking them is into a long square frame of wood, called a

bin, with a cloth hanging on tenter-hooks within it, to receive the hops as they are picked.

The hops must be picked very clean, *i. e.* free from leaves and stalks; and, as there shall be occasion, two or three times in a day the bin must be emptied into a hop-bag made of coarse linen cloth, and carried immediately to the oast or kiln in order to be dried; for if they should be long in the bin or bag, they will be apt to heat and be discoloured. If the weather is hot, there should no more poles be drawn than can be picked in an hour, and they should be gathered in fair weather, if it can be, and when the hops are dry; this will save some expence in firing, and preserve their colour better when they are dried.

Drying. The best method of drying hops is with charcoal on an oast or kiln, covered with hair-cloth, of the same form and fashion that is used for drying malt. There is no need to give any particular directions for making these, since every carpenter or bricklayer in those countries where hops grow, or malt is made, knows how to build them. The kiln ought to be square, and may be of ten, twelve, fourteen, or sixteen feet over at the top, where the hops are laid, as your plantation requires, and your room will allow. There ought to be a due proportion between the height and breadth of the kiln and the beguils of the steddle where the fire is kept, *viz.* if the kiln is twelve feet square on the top, it ought to be nine feet high from the fire, and the steddle ought to be six feet and a half square, and so proportionable in other dimensions.

The hops must be spread even upon the oast a foot thick or more, if the depth of the curb will allow it; but care is to be taken not to overload the oast if the hops are green or wet. The oast ought to be first warmed with a fire before the hops are laid on, and then an even steady fire must be kept under them; it must not be too fierce at first, lest it scorch the hops, nor must it be suffered to sink or slacken, but rather be increased till the hops are nearly dried, lest the moisture or sweat which the fire has raised fall back or discolour them. When they have lain about nine hours they must be turned, and in two or three hours more they may be taken off the oast. It may be known when they are well dried by the brittleness of the stalks and the easy falling off of the hop-leaves.

Bagging. As soon as the hops are taken off the kiln, lay them in a room for three weeks or a month to cool, give, and toughen; for if they are bagged immediately they will powder, but if they lie a while (and the longer they lie the better, provided they are covered close with blankets to secure them from the air) they may be bagged with more safety, as not being liable to be broken to powder in treading; and this will make them bear treading the better, and the harder they are trodden the better they will keep.

Laws relating to hops. By 9 Anne, cap. 121, an additional duty of 3*d.* a pound is laid on all hops imported, over and above all other duties; and hops landed before entry and payment of duty, or without warrant for landing, shall be forfeited and burnt; the ship also shall be forfeited, and the person con-

cerned in importing or landing shall forfeit 5*l.* a hundred weight, 7 Geo. II. cap. 19. By 9 Anne, cap. 12, there shall be paid a duty of 1*d.* for every pound of hops grown in Great Britain, and made fit for use, within six months after they are cured and bagged; and hop-grounds are required to be entered on pain of 40*s.* an acre. Places of curing and keeping are also to be entered on pain of 50*l.* which may be visited by an officer at any time without obstruction, under the penalty of 20*l.* All hops shall, within six weeks after gathering, be brought to such places to be cured and bagged, on pain of 5*s.* a pound. The re-bagging of foreign hops in British bagging for sale or exportation, incurs a forfeiture of 10*l.* a hundred weight; and defrauding the king of his duty by using twice or oftener the same bag, with the officer's mark upon it, is liable to a penalty of 40*l.* The removal of hops before they have been bagged and weighed, incurs a penalty of 50*l.* Concealment of hops subjects to the forfeiture of 20*l.* and the concealed hops; and any person who shall privately convey away any hops with intent to defraud the king and owner, shall forfeit 5*s.* a pound. And the duties are required to be paid within six months after curing, bagging, and weighing, on pain of double duty, two-thirds to the king, and one third to the informer. No common brewer shall use any bitter ingredient instead of hops, on pain of 20*l.* Hops which have paid the duty may be exported to Ireland; but by 6 Geo. II. cap. 11, there shall be no drawback; and by 7 Geo. II. cap. 19, no foreign hops shall be landed in Ireland. Notice of bagging and weighing shall be sent in writing to the officer, on pain of 50*l.* 6 Geo. cap. 21. And by 14 Geo. III. cap. 68, the officer shall, on pain of 5*l.* weigh the bags or pockets, and mark on them the true weight or tare, the planter's name and place of abode, and the date of the year in which such hops were grown; and the altering or forging, or obliterating such mark, incurs a forfeiture of 10*l.* The owners of hops shall keep at their oasts, &c. just weights and scales, and permit the officer to use them, on pain of 20*l.* 6 Geo. cap. 21. And by 10 Geo. III. cap. 44, a penalty of 100*l.* is inflicted for false scales and weights. The owners are allowed to use casks instead of bags, under the same regulations, 6 Geo. II. cap. 21. If any person shall mix with hops any drug to alter the colour or scent, he shall forfeit 5*l.* a hundred weight. If any person shall unlawfully and maliciously cut hop-binds growing on poles in any plantation he shall be guilty of felony without benefit of clergy. 6 Geo. II. cap. 37. By a late act, five per cent. is added to the duties on hops.

HUNDRED. In the time of king Alfred the kingdom was in gross, and then divided into counties and hundreds, and all persons came within one hundred or other.

By stat. 2 Ed. III. c. 12, it was enacted, that all hundreds and wapentakes granted by the king, shall be annexed to the king, and not severed. And by 14 Ed. III. c. 9, that all should be annexed, and the sheriff should have power to put in bailiffs, for which he will answer, and no more shall be granted for the future.

Hundreds are not answerable to persons who are robbed travelling on a Sunday. 29 Car. II. c. 7.

Hundreds are liable to penalty on exportation of wool. 7 and 8 W. III. c. 28.

Hundreds are liable to damages sustained by pulling down buildings. 1 Geo. I. c. 5.

Hundreds are liable for damages by killing cattle, cutting down trees, burning houses, &c. 9 Geo. I. c. 22, and 29 Geo. II. c. 36.

Hundreds are liable for damages incurred by destroying turnpikes or works on navigable rivers. 8 Geo. II. c. 20.

By cutting hop-binds, 10 Geo. II. c. 32. By destroying corn to prevent exportation, 11 Geo. II. c. 22. By wounding officers of the customs, 19 Geo. II. c. 34; or by destroying wood, &c. 29 Geo. II. c. 36.

All monies recovered against the hundred to be levied by a rate. 22 Geo. II. c. 46.

HUNGARY-WATER, a distilled water, so denominated from a queen of Hungary, for whose use it was first prepared.

Quincey gives the following directions for making it: Take of fresh gathered flowers of rosemary two pounds, rectified spirits of wine two quarts; put them together, and distil them immediately in *balneo*.

HURA, a genus of the monadelphia order, in the monœcia class of plants, and in the natural method ranking under the 38th order, tricocœæ. The amentum of the male is imbricated, the perianthium truncated: there is no corolla; the filaments are cylindrical, peltated on top, and surrounded with numerous or double antheræ. The female has neither calyx nor corolla; the style is funnel-shaped; the stigma cleft in twelve parts; the capsule is twelve-celled, with a single seed in each cell. There is but one species, *viz.* the crepitans, a native of the West Indies. It rises with a soft ligneous stem to the height of 24 feet, dividing into many branches. After the flower, the germen swells, and becomes a round compressed ligneous capsule, having 12 deep furrows, each being a distinct cell, containing one large round compressed seed. When the pods are ripe, they burst with violence, and throw out their seeds to a considerable distance. It is propagated by seeds raised on a hot-bed; and the plants must be constantly kept in a stove. The kernels are said to be purgative, and sometimes emetic.

HURDLES, in fortification, twigs of willows or osiers interwoven close together, sustained by long stakes, and usually laden with earth. See **FORTIFICATION**.

HURRICANE, a furious storm owing to a contrariety of winds. See **WIND**.

Hurricanes are frequent in the West Indies, where they make terrible ravages, by rooting up trees, destroying houses and shipping, and even whole plantations.

These dreadful convulsions of nature, Dr. Perkins, of Boston, in America, supposes to be caused by some occasional obstruction in the usual and natural progress of the equatorial trade winds. The reason he assigns for this conjecture is, the more than usual calm which commonly precedes them. In the natural course of the trade winds, the air rises up in the line, and passes off towards the poles, and, in the more contracted degrees of the higher latitudes, takes the course of the west trade-winds, so that could their ascent be prevented through the whole circle of the zone, there would be no more west winds in those latitudes than in any other. Very vio-

lent rains and cold, however, tend to check the ascent of air out of this circle, rather causing it to descend. Great clouds of vapour generate cold and wet, while rain beats down the air; and as these prevent the rising of the air out of the line, so they hinder its usual progress from the tropics on both sides; hence the calms which usually precede hurricanes. Calms, in these tropical regions, are caused by the ascent of the air into the higher part of the atmosphere, instead of its remaining near the line: the accumulation of air above then becomes heavier by the cold which it meets in those regions, and descends into the more rarefied region below. These heavy gales, therefore, will continue to descend till the upper regions are entirely exonerated.

HUSBAND AND WIFE, usually called *baron and feme*, are one person in law: that is, the very being or legal existence of the woman is suspended during the marriage, or at least is incorporated and consolidated into that of the husband, under whose wing, protection and cover she performs every thing. She is therefore called in our law French, a *feme covert*, that is, under the protection and influence of her husband, her baron, or lord; and her condition during her marriage is called her *coverture*.

A man cannot grant lands to his wife during her *coverture*, nor any estate or interest to her, nor enter into covenant with her. But he may by his deed covenant with others for her use, as for her jointure, or the like; and he may give to her by devise or will, because the devise or will does not take effect till after his death. 1 Inst. 112.

All deeds executed by the wife, and acts done by her during her *coverture*, are void, except a fine, or the like matter of record, in which case she must be solely and secretly examined, that it may be known whether or no her act is voluntary. 1 Black. 444.

A wife is so much favoured in respect of that power and authority which her husband has over her, that she shall not suffer any punishment for committing a bare theft in company with, or by coercion of her husband. But if she commits a theft of her own voluntary act, or by the bare command of her husband, or is guilty of treason, murder, or robbery, in company with or by coercion of her husband, she is punishable as much as if she was sole; because of the odiousness and dangerous consequences of these crimes. 1 Haw. 2.

By marriage the husband has power over his wife's person; and the courts of law still permit an husband to restrain a wife of her liberty, in case of any gross misbehaviour. But if he threatens to kill her, &c. she may make him find surety of the peace, by suing a writ of *supplicavit* out of chancery, or by preferring articles of the peace against him in the court of king's bench, or she may apply to the spiritual court for a divorce *propter savitatem*.

The husband by marriage obtains a freehold in right of his wife, if he takes a woman to wife that is seized of a freehold; and he may make a lease thereof for 21 years, or three lives, if it is made according to the statute. 32 Hen. VIII. c. 28.

The husband also gains a chattel real, as a term for years, to dispose of if he pleases by grant or lease in her life-time, or by surviving her: otherwise it remains with the wife. And upon execution for the husband's debt, the sheriff may sell the term during the life of the wife. 1 Inst. 351.

The husband also by the marriage has an absolute gift of all chattels personal in possession of the wife in her own right, whether he survives her or not. But if these chattels personal are choses in action, that is, things to be sued for by action, as debts by obligation, contract, or the like, the husband shall not have them, unless he and his wife recover them. 1 Inst. 351.

By custom in London, a wife may carry on a separate trade; and as such, is liable to the statutes of bankruptcy with respect to the goods in such separate trade, with which the husband cannot intermeddle. Burr. 1776.

If the wife is indebted before marriage, the husband is bound afterwards to pay the debt, living with the wife; for he has adopted her and her circumstances together. 1 Black. 143. But if the wife dies, the husband shall not be charged for the debt of his wife after her death, if the creditor of the wife does not get judgment during the *coverture*. 9 Co. 72.

The husband is bound to provide his wife necessaries; and if she contracts for them, he is obliged to pay for the same; but for any thing besides necessaries, he is not chargeable.

And also if a wife elopes, and lives with another man, the husband is not chargeable even for necessaries; at least if the person who furnishes them is sufficiently apprized of her elopement. 1 Black. 442.

A man having issue by his wife born alive, shall be tenant by the courtesy of all the lands in fee simple, or fee tail general, of which she shall die seized. Litt. 52.

And after her death he shall have all chattels real: as the term of the wife, or a lease for years of the wife, and all other chattels in possession; and also, all such as are of a mixed nature (partly in possession and partly in action), as rents in arrear, incurred before the marriage or after: but things merely in action, as of a bond or obligation to the wife, he can only claim them as administrator to his wife, if he survives her. Wood. b. 1. c. 6.

If the wife survives the husband, she shall have for her dower the third part of all his freehold lands: so she shall have her term for years again, if he has not altered the property during his life: so also she shall have again all other chattels real and mixed: and so things in action, as debts, shall remain to her, if they were not received during the marriage. Id.

But if she elopes from her husband, and goes away with her adulterer, she shall lose her dower, unless her husband had willingly, without coercion ecclesiastical, been reconciled to her, and permitted her to cohabit with him. 1 Inst. 32.

HUSBAND LAND, a term used in Scotland for a portion of land containing six acres of sock and scythe land; that is, of land that may be tilled with a plough and mown with a scythe.

HUSBANDRY, in the general sense of the word, comprehends the whole practice of agriculture; in which we have to consider the nature of the soils we meet with, on and near the surface of the earth. The methods of correcting those which are unfavourable to the production of useful vegetables; the improvement of such as are deteriorated by over-cropping; such implements as are fittest for facilitating the operations of agriculture; the means and powers best adapted for such purposes; the cattle and live stock most profitable to man, whether for labour or more immediate use as food; the grass, grain, roots, and pulse, most beneficial to him; and the minor subjects connected with this important science.

The culture of the earth is coeval with man; his beneficent Creator placed him in a well-stored garden, enjoining him "to dress and to keep it;" and after a fatal lapse of obedience, he was driven from his paradisaical situation, a new injunction was laid on him, "to till" the ground, "that thorns and thistles" may not choke the better productions of it. Adam, "by the sweat of his brow," so cultivated the soil, that it produced a sufficiency for himself and family: his sons he instructed in the art, and they communicated the same to their descendants: and thus the knowledge and practice of agriculture were promulgated through the early ages of mankind.

When the deluge had swept away from the face of the earth every vestige of human art, the ark excepted, Noah and his descendants found themselves under the necessity of reviving the practice of husbandry, as one of the surest means of procuring the necessaries and comforts of life. The methods pursued by the early generations are unknown to us, as are most of the implements which they employed; perhaps the mattock and coulter were their principal tools.

It seems probable that the inhabitants of the ages which immediately succeeded the flood, knew not the proper methods of restoring fertility to an exhausted soil; for we find them frequently changing their place of residence, as their flocks and herds required fresh pasturage, or their tillage land became unproductive. When the descendants of Abraham settled themselves in Palestine, agriculture began to raise itself into importance, and was considered not only as an useful but honourable employment. The Chaldeans, who inhabited the country where agriculture had its birth, cultivated the land with great assiduity, and seemed to have found out the means of restoring fertility to an exhausted soil, having plentiful harvests in succession, so that they were not obliged, as their predecessors had been, to be frequently changing their situation, in order to obtain a sufficiency for themselves and their numerous flocks and herds. The Phœnicians were also remarkable for their skill in agriculture. The Athenians taught the rest of the Greeks the use of corn, and how to cultivate the land that it might produce so wholesome a food. As the arts of agriculture increased, and the blessings they afforded became more generally known, these savage Greeks forsook their acorns, and the wild roots of the field, and applied themselves assiduously to the cultivation of the earth; their kings encouraging such laudable pursuit. The old Ro-

mans esteemed agriculture so honourable an employment, that one of the highest praises which could be given to a man, was that of saying he had well cultivated his spot of ground. The most illustrious senators, in the intervals of public concerns, applied themselves to this profession.

But to bring the subject home to our own country, we find that the art of husbandry was at a low ebb until the fourteenth century; at which time it began to be practised in the midland and south-western parts of England; yet it seems not to have been cultivated as a science, until the latter end of the sixteenth century; when Fitzherbert, a judge of the common pleas, studied the nature of soils and the laws of vegetation with philosophical attention; and in 1534 published his first work entitled, "The Book of Husbandry." Beyond which, small advances only were made in the theory until the time of the commonwealth; when sir Hugh Platt, one of the completest husbandmen of the age, discovered and brought into use a multitude of manures, little thought of by others, for meliorating and fertilizing exhausted soils. At the time of the Restoration, agriculture appears to have suffered considerable neglect, until Evelyn and Tull, by their literary labours, mightily promoted the study. Since their days, many valuable improvements have been made in the practice, and many are the writers who have rendered essential services, by enlightening the minds of their countrymen, and exciting them to emulation. In our own days, with pleasure we behold many respectable agricultural societies established in different parts of the kingdom, greatly contributing to the advancement of the practice as well as theory of agriculture; among which we must particularly notice that of high national concernment, instituted a few years since, under the title of the "Board of Agriculture."

About the year 1790, sir John Sinclair, a gentleman of genuine patriotic philanthropy, conceived an idea that such a board, properly constituted, would be of vast importance to the agricultural interests of the kingdom. Having, with much attention to the subject, matured his plan, and communicated the same to some of his parliamentary friends, in May 1793, "An address from the honourable house of commons was presented to his majesty, entreating that his majesty would be graciously pleased to take into his royal consideration the advantages which might be derived by the public from the establishment of a board of agriculture and internal improvement."

After surmounting the difficulties naturally attending the formation of such an institution, the charter for the same was drawn up, and sanctioned by the authority of the great seal, in August of the same year, and the founder elected president. To this society we are indebted for 80 volumes of the most useful agricultural knowledge, which could be procured from literary men, resident in, or intimately acquainted with the respective counties, under the title of a "General View of the Agriculture thereof, with observations on the means of Internal Improvement." The grand outlines of the plan of these views are, the geographical state of each county, the state of property, farm buildings, mode of occupation, implements, fences, arable

land, grass, orchards, plantations, draining and other improvements, live-stock, rural economy, means of improvement, &c.

A work comprising so many important objects in the science of agriculture, cannot fail of producing national benefits, greater perhaps than have been derived from any other political institution of modern times.

Besides the county reports of agricultural views, the board have published sundry volumes of communications on various topics of husbandry, which have been transmitted to them by writers fully conversant with the subjects of their respective communications. By pursuing such plan for a few years, and publishing to the world such communications, under some systematic arrangement, we may expect that agriculture will become the best understood, and the most accessible of any art in the whole circle of human acquirement.

Soils. A land considered as the basis of vegetation is called soil. The particles of the various solid, as well as less compact bodies, that are met with in nature, and which have been rubbed down and reduced by the successive operations of the atmosphere, and the agency of other natural causes, being mixed and blended together in different ways and proportions, constitute the earthy compounds, which, from their being capable of absorbing, and in some measure retaining, moisture, as well as giving stability, afford the means of support to various products of the vegetable kind, and form the bases of soils in general; while the materials proceeding from the decomposition and decay of numerous organized animal and vegetable substances, uniting with such compounds, compose the superficial layers of rich mould, from which plants chiefly draw or derive their nourishment and support.

Soils being formed in this manner, it is evident they must vary much, both in the qualities and proportions of the ingredients of which they are composed. In one situation or district one sort of material is abundant, and consequently enters largely into the soil; in others it is deficient, while those of other kinds are plentiful, and constitute the principal parts of the soils where they are found. Some situations too abound much more with animal and vegetable matters than others, which produce great diversity in regard to the soils. The harder and more firm substances of nature, being, on account of their structure, reduced more slowly, and with greater difficulty, into the state of earth, generally enter in much smaller proportions into the composition of soils, than those which are of a soft and pliable disposition, and which approach nearer to the quality of earth. Thus argillaceous, loamy, and vegetable matters are found to predominate very much in soils in their primitive state, and, according to their particular qualities and proportions, to constitute very material differences in their properties. Calcareous and siliceous earthy matters are distributed over some districts in great abundance, while in others they enter into the composition of the soils in much smaller proportions, and thus contribute to vary their textures and qualities.

One of the means of deciding in respect to soils, which, in many cases, when properly limited and exercised, by a person of sound

judgment and duly experienced, is certainly not a bad one, though in some respects also defective, is that of determining from the nature of the plants that are naturally produced, and the degrees of their growth and luxuriance. Thus, where plants that are only accustomed to grow in good or peculiar sorts of soil, are met with in their natural and flourishing states in other places, the soils may be concluded to be of this or that kind, according to the circumstances in which they are found. The growth of certain sorts of timber trees and hedges, may also in various instances serve to direct the judgment, and likewise the appearances or colours of the mould in particular instances; the smell and the touch will also help to inform us of the quality of a soil: The best emits a fresh pleasant scent, when fresh dug up; and if due proportions of clay and sand are intimately blended, it will not much stick to the fingers in handling. But, however, that our readers may be informed of some of the leading principles which chemistry employs, in analysing soils, we give him the following, which may be depended on.

1. To ascertain the quantity of water in any soil, take a pound of the soil, spread it very thin before the fire, or in the sun-shine in a warm day, let it lie till it is thoroughly dry; the evaporation of the water will be known by the weight lost.

2. To know if there are any metallic or earthy salts, take a pound of soil, pour upon it a pound of boiling distilled water, stir them thoroughly together, and let them stand for ten minutes, filter off the water through filtering paper, pour into what comes through a solution of the fixt vegetable alkali; if there is any earthy or metallic salt, a precipitation will take place.

3. To know if the salt contained has calcareous earths for one of its elements, take the filtrated solution, pour into it half an ounce of caustic volatile alkali, or continue to drop in this alkali till no further precipitation takes place; afterwards filtrate it, and pour to what filtrates through a little solution of fixt vegetable alkali; if there is any further precipitation, it shews that there is an earthy salt consisting of calcareous earth for one of its elements; if a precipitation took place upon the application of the caustic volatile alkali, it shews that there certainly are earthy or metallic salts.

4. To know if the salt contained is metallic or aluminous, add to the filtrated solution an infusion of galls; if there is any metallic or aluminous salt, a precipitation will take place; if iron, a purplish black; if copper, or allum, a grey: copper may also be distinguished from iron by falling in a blue precipitate upon the application of an alkali, while iron forms a greenish, and allum a white one.

5. To know if magnesia is an element of the salts found, take the filtrated solution, apply to it a solution of galls; if no precipitation takes place, apply caustic volatile alkali, which will precipitate the magnesia if it is an element of the salt contained.

6. To know if a neutral salt is contained, evaporate the filtrated solution with a boiling heat, till the whole water is nearly gone off, and let it stand to cool: if there is any neutral salt, it will crystallize.

7. To know if there is any mucilage, and what quantity, take 30 or 40 lbs. of the soil, boil it in 10 gallons of water for an hour, let the earth subside, pour off the clean solution, afterwards add four or five gallons of water to the earth, stir them thoroughly, let them stand to subside, pour off the water clear, mix it with the former, and evaporate the whole to dryness, putting it into a water bath towards the end of the evaporation; what remains is the mucilage, making allowance for that part of the decoction which was not washed out from the earth, and deducting the saline substances, which will crystalize if there is a considerable quantity, but will be destroyed in the operation, if in small proportion, as they generally are.

8. To know if there is any calcareous earth in the soil, and what quantity, take $2\frac{1}{2}$ oz. of the dry soil, apply to it $\frac{1}{2}$ oz. of muriatic acid, and 4 oz. of water in a glass vessel sufficiently large; let them stand together till no more effervescence takes place; and if it was very considerable, pour in $\frac{1}{2}$ oz. more of the acid, let this stand also till the effervescence ceases, if any arises upon pouring it in, continue to add more acid in the same manner, until what was poured in last produces little effervescence, which is often at the first, and generally at the second or third half ounce. After the effervescence has ceased, put the whole in a filter, let the solution filtrate through; pour half a pint of water upon what remains in the filter, let that filtrate also in the same vessel; add to the solution thus filtrated $1\frac{1}{2}$ oz. of caustic volatile alkali for every ounce of acid used; if any precipitation takes place there is magnesia, earth of allum, or the calx of a metal (generally iron or copper) contained in the soil; after adding the volatile alkali, the whole is to be thrown into a filter again; after the filtration has taken place, pour into the liquor a solution of mild fixt vegetable alkali in water; if there is any calcareous earth in the soil, a precipitation will take place; continue to add the solution of the alkali till no fresh precipitation ensues, throw the whole into a filter, let the liquor filtrate off, pour on by degrees a pint of water, let that filtrate off also, dry what remains in the filter, it is the calcareous earth.

9. To know the proportion of sand and clay, take what remains in the filter after the first solution in the foregoing operation, and by the elutriation separate the sand from the clay, dry and weigh them; if there is any pyrites it will appear in the sand.

In the above processes the principal things to be attended to are, whether there are any metallic or aluminous salts, as these are absolute poisons, and therefore are to be decomposed by quick lime; whether there is such a proportion of neutral or earthy as to be hurtful, in which case the solution in process 2. will taste salt, a soil containing them in so large a proportion will hardly ever admit of culture for grain: whether there is calcareous earth, and in what proportion, as that ascertains the propriety of applying any manure containing it, and the quantity of that manure: what the proportion of sand and clay is which ascertains the propriety of adding clay or sand; whether there are pyrites, as that shows why, and when a soil will be long in being brought into cultivation; pyrites are best destroyed by fallowing, and afterwards applying lime.

The soils of this country have been described under numerous heads, and distinguished by a variety of vague local terms. They seem, however, to be capable of being considered and characterised, as far at least as is necessary for practical purposes, under the distinctions of

| | |
|-------------|-------------------------|
| Clayey, | Gravelly, |
| Loamy, | Peaty or Mossy, and |
| Calcareous, | Vegetable Earthy soils. |
| Sandy, | |

Each of these divisions must of course comprehend several varieties, according to the nature and preponderancy of the different sorts of materials of which they are constituted or composed. By different combinations of these substances all the intermediate kinds of soils are formed; and upon a proper mixture of them, in certain proportions, depends the success of the farmer's industry. Sand, clay, and water, are the grand component parts, whatever colour or texture the soil may happen to have.

Clayey or argillaceous soils. Soils of this kind differ very materially, according to the nature and quantity of the clay that enters into their compositions, and the adulteration which has been produced in it by the intermixture of different earthy matters, as well as various mineral, vegetable, and animal substances. For clays are, in general, far from being pure in the states in which they are found in the earth. They are in many instances united with large proportions of siliceous or sandy matter. On these accounts it is that the clayey soils of some districts are so abundantly fruitful and productive, while those of others are insuperably sterile and refractory.

These facts not only shew that there is a prodigious variety in respect to the qualities of these substances, but that they must afford equal variety to the soils into which they enter, and therefore require to be more closely examined, and more nicely ascertained than they appear yet to have been, before all the varieties of soil usually classed under the denomination of clayey can be well ascertained and understood.

But these substances do not differ only in their properties and qualities, but likewise in their colours, and the closeness with which their particles are united. They are found in their natural states of various colours, such as red, white, blue, and yellow, and of different degrees of density, so as, in some instances, readily to admit of being united with the different materials that are applied, in order to meliorate their conditions; in others they can scarcely be made to join with them by any means in the power of the agriculturist. In soils of the first kind, the quantity of siliceous or sandy matter, in general, bears a much larger proportion to that of the argillaceous or clayey, than in those of the latter, and in many cases too the mixture of other substances is proportionably larger. The nature of the clayey stratum, in respect to its thickness or thinness, as well as its contiguity, or remoteness from springs of water underneath it, is too commonly overlooked in considering these sorts of soils; but all these circumstances demand particular attention, and ought to have considerable influence in directing the means of cultivating and improving clayey soils.

It is obvious, from what has been already advanced, that, notwithstanding the differences that take place from the accidental mixture of different materials, in different degrees and proportions, all the descriptions of this sort of soils must possess more or less of the heavy and adhesive stiff qualities; and that according as these are more or less predominant, due respect being at the same time had to the various other circumstances that have been stated, the business of cultivation and improvement must be varied and applied.

Loamy soils. Loam denotes any soil which is moderately cohesive, that is, less so than clay, and more so than loose chalk. Soils, therefore, of this description admit of considerable variety. The substances that are most commonly found to contribute to the formation of loamy soils, are clay, sand, gravel, and chalk: and as either ingredient predominates, so is the soil denominated, as clayey loam, sandy loam, &c. Clayey loam is moderately cohesive, in which the argillaceous ingredient predominates; so that its coherence is greater than that of any other loam, but less than that of pure clay. Besides the argil silex enters largely into the composition. Sometimes an oxide or calx of iron in small proportion is found blended with the clay and sand. In proportion as the argillaceous or clayey principle diminishes, they recede from the nature of the clayey soils; consequently the nearer the quantity of that substance approaches to that of the others, the stronger and more heavy will the loamy soil be. The differences in the lightness and friability of the soils of this class, in a great measure, depend on the relative proportions of the other ingredients. Where the calcareous ingredient greatly exceeds those of the sandy or gravelly kinds, they are neither so light nor so pulverizable as where they are nearly equal, or where the sandy or gravelly matters considerably predominate over it.

In situations where this sort of soil has been but little disturbed, and consequently little changed by the artificial additions of either animal or vegetable substances, and those which it naturally contained not having advanced to the stage of perfect solution and decay, it is generally found of a light brown or hazel colour; but where much culture has been employed for a length of time, and large applications of animal and vegetable matters frequently made, the natural and artificial materials of these kinds having proceeded more nearly to the state of perfect resolution and destruction, it has an appearance that approaches to black. From these various circumstances the properties of the soils are likewise considerably altered and affected, as well as their colours changed.

From the soils of the loamy class being more friable and brittle, as well as more dry, than most of the clayey ones, they are capable of being tilled with much greater ease and facility, as well as much less strength of team, and at almost every season of the year. And, on account of their property of receiving and transmitting moisture more freely, they are less apt to be indurated by too much dry, or chilled by too much wet weather. Besides, they are more influenced on exposure to the agency of the atmosphere and other external causes, and thereby more

adapted for the promotion and support of vegetation. And as they are found in most cases to be less disposed to the production of weeds, particularly those of the more injurious kinds, they can of course be kept clean with less labour, and without the expensive system of management which is requisite on many other kinds of soil.

Chalky or calcareous soils. Soils of the calcareous kind, which are composed of clay, sand, and chalk, occupy very extensive tracts of land in different parts of the kingdom, and are marked with considerable diversity, as proceeding from the nature, properties, and proportions of the calcareous matter as it exists in them; the substances that are mixed and combined with it; the depth and qualities of the earthy stratum which is placed upon it, and the disposition of the sub-soil or basis on which this is formed and deposited.

Calcareous matter is contained in many different stony substances, besides that of chalk, as marble, lime-stone, coral, and shells of different kinds; and in states of union with other materials, such as sand, the different simple earthy bodies, in different proportions, and in some instances with iron and magnesia. Its capability or powers of imbibing and retaining moisture is considerable, though not so great as that of clay. It burns to lime by proper degrees of heat, and absorbs carbonic acid gas, or fixed air in different proportions from the atmosphere, and returns again to the state of chalk or mild calcareous matter. It is found of very different degrees of hardness and friability, as well as of different states of fineness or pulverization, in different soils of the class to which it belongs. It varies also greatly in its effects in respect to vegetation; from the different matters that may happen to be combined with it in its primitive or original state. It has long been known to the practical agriculturist, that some sorts of lime may be employed in large proportions, while others cannot be used, except in very small quantities, without doing very considerable injury to the soil with which they are incorporated.

Calcareous matter, whether it is in the state of carbonat, or in the more active one of causticity, as quick-lime, seems ultimately to promote the resolution and destruction of vegetable and animal substances; in the latter state, however, it acts with much greater violence on these materials, destroying their organization, and dissipating their principles more quickly, as well as robbing them more completely of the carbonic acid gas, or fixed air, which is so essential, while in the former it operates with great mildness, and only aids the resolution of those substances by gently promoting the process of putrefaction.

The proportions of clayey, loamy, and gravelly ingredients, which are conjoined with the calcareous matters of these soils, are various in different districts; where the argillaceous and loamy materials are comparatively in large quantities, soils of the heavier chalky kinds are formed, and where the sandy or gravelly are predominant, we have the lighter ones. There are also material differences proceeding from the earthy matter with which the calcareous ingredient is mixed in the state of soil. Where the quantity of this is small, and not reduced into any very

perfect state of mould, the soil, as it is evident, must be poor and thin; but where the depth of this superficial stratum is considerable, and the animal, vegetable, and other substances, of which it is composed, is advanced to a more complete stage of decomposition and decay, the soils are more rich and heavy. Some variety is likewise caused by the state of the under-stratum or sub-soil. If it is compact, and much intermixed with siliceous or flinty matter, or have a mortary hardness, it is less favourable than where it is of a more open, brittle, or powdery texture.

Whatever appearances of lightness there may be in chalky soils, they require considerable strength in the team, where the staple or earthy stratum of the lands will admit of their being wrought to a tolerable depth; but where there is a thinner surface of earthy materials, less force of draught will be requisite. In the latter cases, the soil is, however, far more precarious and uncertain, as well as much less productive in respect to the crops that are cultivated upon it, than in the former. As chalky soils are not so liable to be injured by water as others, the business of tillage is much less impeded from that cause; but a dry season sometimes renders them so hard as to be totally incapable of being broken up, until they have been moistened by the falling of a considerable quantity of rain.

Sandy or siliceous soils. Sands seem to have been gradually formed by the attrition and rubbing down of the various solid substances that are found in nature, especially such as are of the siliceous, calcareous, and stony kinds, and are of different degrees of fineness as they approach the size of gravel. They are also met with of various colours and appearances in different regions or tracts of country, such as white, dusky brown, yellow, and red. These differences, as well as those which respect their weight, tenacity, and other properties, depend on the nature and proportions in which many other materials enter into combination with them.

Where the proportions of clayey, loamy, or other earthy substances with which they are mixed, approach nearly to that of the sand, the heavier sorts of sandy soils are formed; but where these enter only in very small quantities, we have the light sandy soils; and where they are hardly met with at all, the soil is a loose blowing sand, most commonly of a white or brownish appearance. The portions of vegetable matters that are intermixed with different soils of the sandy kind are not less various than those of the clayey and loamy, from which considerable differences of quality are produced. These differences in their textures and compositions also introduce others which respect their powers of admitting and retaining heat and moisture. The openness and want of adherence in such soils, while they allow of the admission of heat and water more readily, permit them to be carried off with greater ease and expedition, they are therefore less permanently benefited by their influence than the closer and more adhesive soils.

The light, open, and porous texture of sandy soils renders them much more easily cultivated and kept in order than those of the strong and close kinds; consequently the farms where they prevail are generally large;

and when properly prepared, they are better adapted for the growth of many sorts of crops, such as those of the bulbous and tap rooted sorts. They have also another advantage, which is that of pushing forward the crops with more expedition. Whatever inconveniences attend them are mostly such as proceed from the want of a sufficient degree of cohesion among their constituent particles and solidity of texture. On these accounts they often counteract the best and most judicious management. The roots of the crops are liable to become naked and exposed from storms and various other causes; and if grain, to fall down and be lodged so early in the season as to render them of little value.

Gravelly soils. In the state of gravels which contribute to the formation of this class of soils, there is a variation of size in the pieces or particles of which they are composed, from that of a very small pea to the largest cockle. Where they become of still larger dimensions they are termed stones or rocks, according as they are in small portions or large masses; and the soils are then said to be stony or rocky, as the circumstances of the different cases may happen to be.

The beds of gravel, whether they are of the larger or smaller kinds, are mostly either of the siliceous or flinty kind, or of the calcareous or chalky; but the stones and rocks are of very different kinds. With these dissimilar substances, some others in different states of reduction and pulverization are blended and united in various proportions, so as to constitute gravelly soils that differ considerably in their textures and other properties. The chief of these are loams, and the mould or earthy matter formed by the destruction and decay of numerous animal and vegetable substances.

The gravelly mixture is sometimes also found to approach nearly to the surface, while at others it recedes considerably from it. In some instances springs rise immediately underneath; in others they are at a great depth. The bottom, or sub-soil, is likewise various; in some cases it is stony and rocky, in others it is clayey, or a rocky gravel, and sometimes sand, &c.

The open porous nature of gravelly soils disposes them to admit moisture very readily, as well as to part with it with equal facility; from the latter of which circumstances they are subject to burn, as it is termed, in dry seasons, which is not the case in the heavier or more retentive sort of soils.

Gravelly soils, from the lightness of their texture, and their not affording great resistance, except where the stones are large, or there are rocks, are not expensive or difficult in the means of cultivation. All the necessary business of this sort is capable of being carried forward with much ease and expedition, and the lands are in general soon brought into the proper states for the reception of crops.

Peaty or mossy soils. These soils consist chiefly of the roots of decayed vegetables, mixed with earth, mostly argillaceous, and sand, and a coaly substance derived also from decayed vegetables. They differ, like all the other kinds of soils, according to the nature of the ingredients of which they are constituted or composed, and the proportions in which these are found to prevail in them.

Where the vegetable or peaty material predominates but little over the other substances with which it is mixed and incorporated, the lighter sorts of peaty, moory, or heathy soils, are formed; but where the other matters bear only a slight proportion to it, the deep and heavy, peaty or mossy, soils present themselves. In different districts the peaty matter is found of different depths, and of various degrees of density or closeness of texture, probably proceeding from some original differences in the vegetable substances from which it was formed, or the greater advances which it has made to the state of perfect decomposition or decay. The sub-soil in most of the deep mossy districts is of the clayey kind, more or less stiff and heavy, over which the peaty or mossy material is deposited, generally in a sort of stratified order; the first layer of which being commonly not more than ten or twelve inches in thickness, exhibits the appearance of a rich brown earth, in all probability from the incorporation of the loamy or clayey matters, with the peat or vegetable earth, lying immediately upon them, and constituting originally, perhaps, the surface of the ground. The layer that succeeds to this is mostly of a dark colour, and considerable thickness, apparently formed of a great variety of vegetable materials in the more perfect stages of resolution and decay, united together by time and other circumstances with more or less compactness and solidity. The uppermost stratum, or that which is placed upon this dense, peaty matter, is, in general, of very pale colour, and very light spongy texture, arising possibly from the grasses, leaves, and other vegetable substances, of which it is formed, not having attained that state of decay which constitutes the darker sorts of peaty earth.

But in the more superficial peaty soils, little or nothing of this stratified appearance is met with. A coat of peaty earth, differing greatly in thickness according to the peculiarity of the situations, and other circumstances, is formed by a great length of time from the destruction and decay of successive crops of grasses, leaves and substances of the heathy or other kinds, and deposited upon, and intermixed with, the various harder materials of the soils which happened to be underneath them. By these means much variety is produced in the soils. Where the under-strata of earthy matter are tolerably good, and the crops of vegetables large and luxuriant, the better sorts of light peaty soils seem to be predominant; but where the quality of the under-strata are indifferent, and the vegetable products scanty, as well as feeble in their growth, and principally of the heathy tribe, the poor peaty and heathy, or moory soils, are met with.

All peaty soils seem to be thus gradually formed by the deposition of vegetable matter, supplied by the dissolution and decay of aquatic and other plants that grow in low moist situations, as well as substances of other kinds brought down by water, from the high grounds in their neighbourhood, in the states of solution and diffusion, and gradually deposited from it on its becoming in a state of stagnation, by means of obstruction and stoppages proceeding from different causes.

From the nature of the composition of these soils, it is obvious that they must be

very retentive of water, especially where they are of any great depth. Hence they seldom or ever become free from the excessive quantities of moisture, with which they are loaded in the rainy seasons.

Vegetable earth or soil. This kind of earthy material constitutes the superficial bed or stratum, in which plants for the most part vegetate in every sort of soil, and differs very much in different places, from the variations that take place in its depth, and the greater or less progress that has been made in the several substances of which it is composed, to the stage of perfect decomposition or decay.

Some variety may likewise be caused by its being more intimately or more loosely mixed and blended with the other bodies that are found in soils. It seems probable too, that the earthy matter which is formed from the destruction of some sorts of vegetable substances may be better suited for the purposes of vegetation than that which proceeds from others.

Vegetables, from their containing a considerable portion of mucilaginous matter in a state of mixture with their other substances, become, in some measure, capable of solution in water, though the external surfaces of living plants, on account of the resinous and animalized materials that enter into their composition, are protected from its operation. From the former circumstance, and that of earthy matters being contained in them, which had been taken up in the state of solution with their fresh juices while growing, it is evident that large quantities of vegetable mould must be continually formed and deposited on lands by the natural decay of such substances.

But the formation of vegetable mould or earth is farther effected by means of the putrefaction or dissolution of such vegetables as are cut down, or otherwise destroyed, on the surface of the ground, and the application of various kinds of dung and composts. Where these have been in great abundance for a long time, there is mostly a deep rich surface soil of this earth; but where few vegetable products, and those of the less luxuriant kind, have been left to undergo the above process, or little assistance given by means of manures, the crust of surface mould is generally thin and poor. The resolution of vegetable matters is greatly promoted by a proper degree of moisture and heat, as well as a suitable state of the air.

From the preceding account of soils, we may perceive that those are the best which contain the greatest store of those principles which constitute the pabula of vegetation. Such are calcareous soils, in which carbon must exist in large quantities, from the natural attraction of lime for carbon, and where there will be a constant supply by means of this attraction. Soils formed from the decomposition of animal and vegetable matters, are in their natures eminently favourable to vegetation; for they contain hydrogen and carbon combined, together with the remains of animals and vegetables, as yet only tending to decomposition, with various salts resulting from the decomposition of animal bodies, water, earth, and gaseous principles.

Improvement of soils. From various causes, we perceive that some sorts of soil are less adapted to a vigorous production

tion of vegetables than others. To improve the less fertile is a main branch of husbandry. According to circumstances, various methods must be employed; such as commixing one kind with another; draining such as are too retentive of moisture; irrigating such as are by nature too dry; and refreshing those with manures whose fertility has been exhausted.

Of commixing various soils. Chemical analysis has shewn that substances of the calcareous kinds are the most beneficial in bettering the condition of clayey soils. Where the deficiency is in the want of calcareous matter, lime-stone, gravel, and calcareous marls are the most proper. If, however, these substances cannot be conveniently procured, a mixture of the coarser sands with lime and dung may be employed; or even coal ashes, sea sand, or chalk in the state of coarse powder may be advantageously used.

Loamy soils stand not in need of so much commixture with other substances as clayey soils; the soil of ponds, ditches, or even a small proportion of clayey soil may however be applied to advantage, and especially dung.

Chalky or calcareous soils of the heavier sorts may be benefited by the application of sandy loams; the lighter sort, by clay, dung, and argillaceous marl.

Sandy soils may be improved by applying calcareous marl, argillaceous and loamy ingredients, and by the use of the fold.

Gravelly soils of the calcareous kind may be improved by clay, clayey loam, or chalk.

Peaty soils, after being properly drained of their superfluous moisture, may be improved by the application of gravel, common sand, coarse earth, chalk, calcareous marl, dung, or sea sand. See DRAINING.

Irrigation or watering land. The systematic manner of watering meadow land, as now practised, is of modern invention, but of material importance to that farmer who possesses land of proper quality, and commands a stream of water suitable to the purpose; as he will be enabled to procure an earlier and fuller crop of grass than he could by other means.

Water, independent of any substances it may hold in suspension, is of universal utility in vegetation; being composed of two chemical elements (hydrogen and oxygen) which are highly favourable to vegetation, and directly and powerfully nutritive to plants. It enters, even undecomposed, as an aliment into the organization of vegetables. It is the only vehicle by which nourishment can be conveyed from solid bodies to plants. And whatever gaseous food the roots of vegetables receive, it is presented to them by the intermediation of water. Although thus beneficial when administered in season and due proportion, yet an excessive affusion of water tends to the destruction of many of the better grasses, and to the nourishment of rushes, mosses, sedge, and other aquatic weeds. A gentle affusion of this fluid, dispensing itself in all directions, never stagnant, never running with great impetuosity of current, more copiously applied in the light and under the heat of the sun than in the dark, operates with the best efficacy, as a promoter of vegetation.

The idea of watering meadows, so far as it relates to bringing the water upon the land, was undoubtedly taken from nature. It must have been always observed that winter floods produced fertility, provided the water did not

remain too long on the land. The idea of taking the water off the land at will, and bringing it on again at will, is the effect of art; and the knowledge of the proper seasons to do this, is the effect of observation.

Suitable soils for water meadows are such as are of a sandy or gravelly nature, especially in the nearest sub-soil. A bed of flints, or loose gravel, is the most desirable. It is also observable, that whatever may be the most abundant grasses in a meadow before irrigation, those kinds will always predominate which best agree with the soil and the water, provided the supply of water is regular and constant every winter.

There are two distinct methods of watering land, according as a less or greater quantity of water can be commanded. If the water is taken from a streamlet, near to the spring head, and the quantity small, only a small portion of land can be irrigated at a time, the water carriages and floating sluices are laid out, and cut in a form which (provincially) is by some called catch-work, by others frame-work. But where a river or large stream can be commanded, the work assumes another appearance, and being of greater power than the foregoing, is called flowing-work.

It is necessary, before entering upon works of this kind, to consider whether the stream of water to be employed will admit of a temporary weir or dam to be made across it, so as to keep the water up to a proper level for covering the land, without flooding or injuring other adjoining grounds; or if the water is in its natural state sufficiently high without a weir or dam, or to be made so by taking it from the stream higher up more towards its source, and by the conductor keeping it up nearly to its level till it comes upon the meadow or other ground. Further, if the water can be drawn off the meadow or other ground as rapidly as it is brought on.

This is to be done by the use of a spirit level, beginning from the highest part of the land that the stream can be commanded from, where the grounds on the different sides are the property of the same person, and weirs, or other works, as has been just observed, can be carried across the streams for the purpose of forcing the water, either wholly or in a partial manner, into a different course. After it has been raised as high as possible in this way, the level is to be formed from the surface of the water, carrying it on what is termed the dead level, allowing some small degree of depression for the flow of the current.

After this has been done, the land on the different sides of the stream, below the lines set out by the level should be minutely examined and inspected, as the whole may be irrigated if the command of water is sufficient. The extent that can be properly performed must however depend much on the degree of fall or descent from the entrance of the water and its out-fall, as well as on the declivity of the more elevated parts of the ground.

The next circumstance of importance is that of deciding where to commence the business. This must depend on various points, which can only be settled by the judgment of the operator. If there is a full supply of water, the whole should be covered; but in the contrary case, the expense of cutting the

mains or carriers on such levels in a sufficient manner should be considered; and where one side of the stream is better adapted to the purpose than the other, that on such side should be the first executed. And if the land most adapted to the purpose of watering is at much distance from the place whence the water is first taken, and there is not a supply for the whole of the land below the line of level on one of the sides, the expense of forming the carrier should be put in comparison with the greater advantage of irrigating the most suitable grounds, in preference to others that are nearer, without possessing equal advantages. It mostly happens that the beneficial consequences of irrigating at command are such as to overbalance that of forming the mains or carriers. Besides, though the supply of water may be insufficient in such seasons as are very dry, as it may be abundant in the winter time, the simply covering the land at that period may be more than adequate to the expense of the business, which is a circumstance that may render it more beneficial to lengthen the carriers, than by having them shorter to be confined to the watering of such lands as are less proper for the purpose. It is probable also, that in particular cases the winter irrigation may extend through the whole of the level that has been set out.

Where it can be done, it is best to begin with such parts as are contiguous to, or approach the nearest the mains or carriers; and after having passed the water over them, to mark the lowest places, where it can be carried off to the best advantage; and from such parts it should then be seen to which other lands the water can be conducted with the greatest facility and benefit. Where the natural shelving of the ground is considerable, less care is necessary; but where this is not much, it may often be requisite to convey the water in a slanting direction for a considerable way, before lands sufficiently low for being covered by it are met with; as in this sort of business it is invariably necessary, in order to prevent the waste of water, to proceed with that which is first made use of to its final outlet into the river before the works on other divisions are commenced.

When the piece of ground to be floated is so much upon the level that the descent cannot easily be determined by the eye, it will be necessary to take an accurate level, and compare the highest part with the stream intended to be used, by which the degree of fall from the surface of the water to the highest point of the land will be ascertained; and in order to convey the water to this point, should it be distant from the stream, the sides of the ditch or canal should be sufficiently raised for the purpose not to keep the water in a dead level, but with such degree of descent as the two points will admit of. In the operation of cutting this canal or main feeder, it will be easy to preserve the proper degree of fall, having previously ascertained the length, for instance, in cutting 50 yards with a fall of five inches, it will be obvious that in every ten yards a descent of one inch should take place, this is necessary to keep the water in a constant lively motion. In some cases it may be necessary to have two main feeders, in order to effect a more equal distribution of the water; the depth and width of which feeders must be regulated by the supply re-

quisite for the smaller gutters. Near to the mouth of the canal or feeder it will be proper to have a flood-hatch or clow, by which the water may be admitted or excluded at pleasure.

In forming the floating gutters, it is perhaps the best method to cut them at right angles, or nearly so, to the feeders; however, where the surface is uneven, in order to preserve a regular descent, a different direction must be given to them, the distance from each other being about ten yards, and the gutters becoming, as has been observed, gradually narrower as they recede from the main canal or feeder. The object in view being to throw the water as evenly over the surface as possible, these gutters should be so constructed that the water which has been introduced may overflow their little banks rather than run rapidly along the bed. Obstructions may sometimes occur, such as low parts, or deep ditches, over which a pipe or spout may easily be made to continue the progress of the water; and such as proceed from ridges, roads, or small eminences, by trunks or other contrivances made to convey the water underneath them.

It has been observed, that there are two distinct methods of watering lands, catch-work and flowing. The methods of making such works may be thus described. From the spring at A, Plate Husbandry, fig. 13, take the level towards C, to include as much of the meadow BCDE as possible. Cut the trench or main drain AC of a width and depth sufficient to take all the water issuing from the spring, and convey it to the proposed meadow. Cut also the carriage gutter of a sufficient depth to take off all waste water which may fall into it; and also float sluices, &c. laid out by a level, placing sods taken from the sluices on the lower side. Was the meadow small, of a smooth surface, and regular declivity, the water might be let out of the main drain at different places, and so water the whole at once; but as these favourable circumstances seldom occur, recourse must be had to the floating sluices above mentioned, which must be cut at proper distances, such as 10 or 12 yards, according to the declivity of the land; the catches or frames may be about 30 yards apart.

If the meadow is large, it must be divided into catches or frames, by several carriage gutters, as in fig. 14, and a frame or two watered at a time, according to the body of water which can be commanded; and when the water is withdrawn thence, it may be conveyed to other frames.

In meadows thus watered from springs or small streams, it is of material consequence that the works should be kept as dry as possible between the intervals of watering; and as such situations are not affected by floods, and generally have but little water, they must be rewatered the more frequently; and as the top works of each frame will be in the way of getting more of the water than those lower down, care must be taken to give the latter a longer time, so as to make them as equal as possible.

Flowing meadows described. The other kind of water meadows, viz. those usually called "flowing meadows," require much more labour, and system, in their formation

than the foregoing. The land applicable to this purpose being frequently a flat morass, the first object to be considered is, how the water is to be got off when once brought on; and in such situations this can seldom be done without throwing up the land in high ridges, with deep drains between them, as *a, b, c, d*, fig. 15. plate 6. A main carriage AB being then taken out of the river at a higher level, so as to command the tops of these ridges, the water is carried by small trenches or carriages along the top of each ridge, and by means of moveable stops of earth is thrown over on each side, and received in the drains below, from whence it is collected into a main drain CD, and carried on to water other meadows, or other parts of the same meadow below. One tier of these ridges being usually watered at once, is generally called "a pitch of work," and it is usual to make the ridges 30 or 40 feet wide; or, if water is abundant, perhaps 60 feet, and 9 or 10 poles in length, or longer, according to the strength and plenty of the water.

It is obvious, from this description, that as the water in this kind of meadow is not used again and again, in one pitch, as in the catch meadows, that this method is only applicable to large streams or to vallies subject to floods; and as these ridges must be formed by manual labour, the expence of this kind of meadow must necessarily exceed the more simple method first described; and the hatches that are necessary to manage and temper the water or rivers, must be much more expensive than those in small brooks.

Management of water meadows. As soon as the after-grass is eaten off as bare as can be, the manager of the mead, (provincially "the drowner") begins cleaning out the main drain, then the main carriage, and then proceeds to "right up the works," that is, to make good all the water carriages that the cattle have trodden down, and open all the drains they may have trodden in, so as to have one tier or pitch of work ready for "drowning," and which is then put under water (if water be plenty enough) during the time the drowner is righting up the next pitch. In the flowing meadows this work is, or ought to be, done early enough in the autumn, to have the whole mead ready to catch, if possible, "the first floods after Michaelmas," the water being then "thick and good," being the first washing of the arable land on the sides of the chalk hills, as well as dirt from the roads, &c.

The length of this autumn watering cannot always be determined, as it depends on situations and circumstances; but if water can be commanded in plenty, the rule is to give it a good soaking at first; perhaps a fortnight or more, with a dry interval of a day or two, always taking the water off at the first appearance of white scum; after which, the works are made as dry as possible, to encourage the growth of grass, and to allow the land to pitch or sink close together.

Whilst the grass grows freely, a fresh watering is not wanted, but as soon as it flags, watering for a few days is necessary. In the months of October, November, or December, some meadows will bear the water for three weeks, which in February or March will not bear it one week, and in April or May not three days.

VOL. I.

In all cases where the watering system is undertaken, except in the time of floods, it may be highly useful to disturb the mud and dirt in the bottom of the main carriers, or drains, before watering; a practice frequently adopted on the continent. Lime has also been thrown into these cuts by some irrigating farmers, and raked with a heavy harrow, or other implement at the bottom, which is a process that will be found to add considerably to the manuring quality of the water. It is probable that many other substances might be employed in the same way, and be thus spread over the surface of grass lands in a minute state of division, with vast advantage in promoting vegetation.

The great degree of verdure and luxuriance which almost immediately succeeds the occasional covering of grass lands with water, sufficiently demonstrate the power which it possesses in promoting vegetation. It is a means of fertility that has been employed for ages in more warm climates, with the most beneficial consequences in increasing the quantity of vegetable produce. But though it has been long in use in other countries, and of late more particularly attended to in this, the principle on which it produces its effects does not seem to be fully understood. In speaking of manure as the food of plants, we have already noticed some of the properties of this fluid that may be useful in the vegetable economy when taken up by the fibrous roots of plants; and there are still other ways in which it would seem to be advantageous in forwarding the growth of grass crops.

Winter and spring are the two seasons when meadows are usually watered, as from the month of November till the beginning of March; the experience of the operator can alone regulate this proceeding as to the length of time they should remain under water. In some districts the water is allowed to flow over the fields for several weeks together, with only the interval of a day or two occasionally; in others, the practice is to flood them the alternate weeks. When frosts set in, floating is usually suspended; but it has been remarked, that in such cases the succeeding crop of grass has been abundant. As the spring advances, much less floating is found to be necessary. However, in all cases, when floating is performed to advantage, the meadows should be laid dry between every watering.

Manures. An increased population requires more abundant stores of food for man, and the beasts immediately under his command, than were before necessary: to this end, where the extension of land cannot be obtained, recourse must be had to the enriching of that which is already in possession, whenever it becomes deteriorated by constant and heavy cropping, with such plants as exhaust the pabulum of vegetables; and also to improve such soils as are by nature less adapted than others to the production of advantageous crops.

Besides the methods we have already spoken of for the improving of lands, mankind have discovered various substances, which, when judiciously applied, possess the power of encreasing the fertility of soil in a wonderful degree. These substances are numerous, and always near at hand. They arise

from the decomposition of animal and vegetable matter, and from the agency of fossil and saline substances.

From the changes that are constantly taking place among bodies in nature, and the new combinations which are formed in consequence of those changes, a great variety of matters are unfolded, elaborated, and prepared for the nourishment and support of vegetable life.

Some of the substances which contribute in this way possess considerable fluidity and volatility, such as water, and various gaseous materials, as oxygen, hydrogen, azote, and carbonic acid, in different states of combination. While others are more gross and heavy, and require to be applied and incorporated with soils, or spread out upon their surfaces, in order that they may produce their effects in promoting vegetation. It is principally to these, as being the means of sustaining different sort of plants as crops, that the term manure has been given by practical writers on agriculture; though it is extremely obvious that they must undergo different changes, and be resolved into their more elementary principles, before they can be taken up, and contribute to the increase and support of vegetables. In the various materials which the art and industry of mankind have rendered capable of being beneficially employed in this manner, there is great diversity; some are found to yield the matters which are necessary for the support of plants much more readily and more abundantly than others, as animal, vegetable, and all such substances as are rich in mucilage, saccharine matters, and calcareous earth, and readily afford carbon, phosphorus, and some aerial fluids; while others that are greatly deficient in all or many of these principles, or do not readily part with them, are found to be of much less utility, when employed in the way of manures. This is probably a principal reason why some sorts of manures, or substances, when put upon grounds, are so greatly superior to others, used at the same time, and in the same manner and proportion.

There are, however, many other ways in which substances, when applied to soils, may render them more fertile and productive, and contribute to the aid of vegetation. Some, besides furnishing such matters as are suitable for the purpose of promoting the growth of plants, are known to add considerably to the quantity of vegetable and other matters contained in the soils on which they are placed, and thereby provide a more suitable and convenient bed for the reception of the roots of plants; others contribute little in this way, but operate chiefly upon such materials as are contained in them, breaking down their organization or texture, and thus setting at liberty different volatile and other ingredients, by which new compounds are formed, and brought to such states as are the most adapted to the support of vegetable life; others again act principally by producing certain changes and alterations in the constitution or texture of soils, such as rendering them more open and porous, or more stiff and compact, and by such means bringing them into the most proper conditions for the bearing of different vegetable productions; and there are still others that contribute in all or several of these ways at the same time.

Substances of the animal kind, when reduced by the process of putrefaction, or other means, into a soft, pulpy, or mucilaginous state, are found by experience to afford those matters which are suited to the nutrition and support of plants with greater readiness, and in more abundance, than most other bodies that can be employed. By chemical analysis it has been seen that the component materials of these substances, so far as agriculture is concerned, are principally water, jelly, or mucilage, and saccharine oleaginous matters, with small portions of saline and calcareous earthy substances. Hence animal matters, though they agree in some circumstances with vegetable productions, each having, in common water, saccharine, and calcareous matters, are far more compounded; and in animal substances, some of these materials are in large proportion, while in vegetables they only exist in a very small degree; and the jelly, which in some measure resembles the gum and mucilage of plants, differs likewise from them, in its having much less tendency to become dry, as well as in its property of attracting humidity from the atmosphere, and of running with great rapidity into a state of putrefaction and decay.

All these principles of animal substances are resolved by their ultimate decomposition into other matters, such as the different gaseous fluids that have been mentioned above, carbon, phosphorus, lime, &c.

Animal substances of every kind, on being deprived of their vital principle, have a quick tendency to take on or run into the state of putrefaction; a process which is considerably affected and influenced by the circumstances under which it is produced. But in the horny and more compact animal matters, this tendency to putrefaction and decomposition is, under similar circumstances, much less rapid than in such as are of a less firm and dense texture.

Hard animal substances. In the matters of this sort that are employed as manures, there is considerable differences in respect to their texture and firmness, some being quite firm and solid, such as bones, horns, hoofs, shavings of horn, and some other similar substances, while others are more soft and pliable. The bones of all animals are capable of affording much nutritious matter to plants, but those which are procured from cattle that have been killed when fat, are the best for the purposes of manure. Those which have been boiled are far inferior, in this view, to those which have not undergone that process, as by such means they are principally robbed of their oily and mucilaginous properties, and consequently must yield much less nourishment to the immediate crop, whether it be grain or grass. All these sorts of substances require to be ground down in mills constructed for the purpose, or otherwise reduced into small pieces, before they are laid on and mixed with the soil. They are excellent for potatoes.

These substances are constituted of a considerable proportion of mucilaginous or gelatinous matter, a slight portion of fat, and an earthy salt composed of the phosphoric acid and calcareous earth. If great heat be applied, they afford a large quantity of hydrogen gas, carbonic acid gas, and a volatile alkaline liquor. From the nature of

these different principles, it is evident that some sorts of substances may be blended and united with the reduced particles of bony matters, so as to promote their effects, as manures, in a considerable degree, such as lime, chalk, peat, earth, and good vegetable mould, in suitable proportions, as by such means new combinations may be formed highly favourable to the process of vegetation.

Soft animal substances. There are various matters of this nature that may be of use for the purpose of improving land as manures, some of which have yet been but little attended to by the farmer. Of this sort are greaves, or the residuum which is left after the making of candles, and the scum which is collected in the boiling or refining of sugar.

Different trials with the former have fully convinced us that it is a substance that possesses great powers when employed as a manure. And although it is a substance which is generally procured at a high price, from its going a great way, and being a lasting manure, it may probably be more frequently had recourse to than has hitherto been the case. It is mostly procured in the state of hard compressed square cakes, though sometimes in a soft condition, without having undergone any pressure. When in the former state, the cakes must be broken down and reduced into as great a state of division as possible, which may be rather a troublesome and expensive process, except a mill, or some proper machine for the purpose, be employed. But when it has been even reduced to the finest state possible, it will still be improper for application as a manure, until it has been mixed and incorporated with a pretty large proportion of some rich earthy substance with which it may combine. Excellent for turnips.

A combination of lime and greaves, mixed with mould from the headlands, in the proportion of about 50 bushels of lime to a ton of greaves. This composition resembles sugar scum, which consists of lime and bullocks' blood.

Lime might thus be combined with bones or woollen rags, or with a compost of earth and night-soil; and would certainly greatly facilitate their conversion into manure, as well as render them more active in producing their effects in the support of vegetable crops. And by some of their properties being absorbed by the lime, during the time of their decomposition, and afterwards parted with more slowly in the soil, they may also by such means be, probably, rendered more durable and lasting, as manures.

There are still more substances of the animal class, such as the blood, serum, wool, hair of animals, refuse of glue-makers, the cuttings of felt-mongers, the clippings of furriers, the scrapings of oiled-leather, and the chips or waste of shoe-makers, which may be made use of as manures, when they can be collected in sufficient quantities. These animal materials, from their abounding in mucilage and oil, their great attraction for moisture, and their being readily soluble in water, contribute quickly to the support of vegetation, but are not probably so durable in their effects upon land as many other substances. Hence they should only be made use of with a view to the immediate crop, which, we believe, is pretty much the case in those places

where they can be obtained in such quantities as to be employed for the purposes of agriculture.

Various animal substances of the fish kind, as the blubber remaining after the preparation of oil from the whale, and other large fishes, and different sorts of small fish, both of the shell and other kinds, may be employed as manures; and also the offals of such animals, where they can be procured in a large quantity, as in large towns, sea districts, and where they are cured or prepared in great numbers for the market.

These substances may be readily reduced to that state which is proper for manure, by mixing with them a small portion of the carbonate of lime, and afterwards, according to circumstances, a quantity, two or three times more than the whole, of good vegetable mould.

The refuse of slaughter-houses and butchers' shops may likewise be prepared and made use of in a similar manner to that of fish. For as the manures that are formed from these animal materials are capable of affording much elastic volatile matters during their decomposition, they of course require to be well mixed and blended with such earthy substances as they can combine with, and render soluble, and in proportions suited to their powers, in order to produce the most beneficial effects on vegetation.

Animal dungs. The animalized substances that are, however, most generally made use of as manures, are the excrements of various kinds of animals, which are found in very different conditions, or states of preparation and richness, proceeding in some measure from the kind of food on which the animal has been fed, the matters with which they are incorporated, and the texture of the substances themselves.

The dung of fat animals is unquestionably more rich, and consequently possesses greater powers of fertilization than the dung of lean ones; and that the quality of the dung of every sort of animal will in a great measure be proportioned to the goodness or poverty of its food. Thus, when the animal is fed on oily seeds, such as lint, rape, and others of a similar nature, it will be the most rich; when kept on oil-cake, or those seeds which have been deprived of part of their oily matter, the next so; on turnips, carrots, and such-like vegetable roots, the next; on the best hay, next; on ordinary hay, next; and on straw, perhaps, the poorest of all.

The urine of animals appears to be a more perfect extract from the animal system than the other; it is therefore surprising that this valuable substance is not more attended to by agriculturists. Let it be mixed with the dung-hill, or else carted to the field after it has passed through the putrefactive fermentation. Its effect on land is immediate.

Some manures of this kind, such as the soil of privies, is sometimes met with in a state fit to be applied to the ground, when not much mixed with fluid matters, such as urine. It most frequently happens, however, that it is in such a liquid state as to require other more solid substances to be blended with it, before it can be conveniently applied to the soil. In doing this, too little regard seems to have in common been paid to the choice of the most proper materials; but it

is obvious, that such as can be the most fully acted upon, and the most readily converted into the states suitable for affording the nutrition of vegetables, by the principles of the matters thus employed as manures, must be the most adapted for the purpose, as well as the most beneficial. When, therefore, the manure made use of in this way is either wholly or principally constituted of such animalized matters, as from their fluidity are in an improper state or condition to be set on land without having other substances previously mixed with them, such peaty, boggy, or black vegetable earths should be chosen as contain large proportions of matter, which the ammonia or volatile alkali so abundantly provided by the decomposition of such substances may exert itself upon, and reduce into that state of solubility which is suitable for promoting the growth of plants.

The results of experiments attentively made in this way, indeed, clearly demonstrate that an inconceivable loss is incurred by the inconsiderate practice of exsiccating human excrement, as well as the negligent custom of permitting the gaseous or liquid parts of dung heaps to evaporate or run away. The trials which we have been enabled to make also lead us to suspect that it is a much more wasteful practice to apply these liquors to ground in their uncombined state, than in conjunction with such earthy materials as have been mentioned above. Besides, much of them must be imperceptibly carried off by the process of evaporation, even when they are carried out in the most favourable seasons of the year; and they cannot in this way always be made use of on those soils that contain a sufficient quantity of those earthy materials or principles with which they can readily form combinations, and exert their most beneficial and fullest effects. It may be demonstrated, by experiment, that yard and stable dung should be applied to the land in its half decomposed state, and not be suffered to remain in heaps until the putrefactive fermentation has reduced it to over putridity.

We are decidedly of opinion, that the soil of privies is a manure of the most enriching kind, but that its effects are not so lasting as those of many other substances. In some trials which have been lately made with it, it has produced such astonishing fertility, as induces us to conclude that it exceeds all other sorts of manure that can be put in competition with it for the first year after its application. The second is of some service, but in the third its effects nearly, if not quite, disappear. The circumstances which render this sort of manure so immediately active in promoting vegetation, and so quickly deprived of its beneficial influence, would seem to be from the great quantity of elastic principles which it contains in a loose state of combination, and the small quantity of earthy matter which it is capable of supplying to the soil, by the last stages of decomposition or decay.

This view of the nature of the manures afforded by different animals, should lead the practical agricultor to be more attentive to the subject, in order that he may render them more abundant, and be capable of employing them under the most favourable circumstances, which cannot be the case while they are, as at present, indiscriminately mixed and blended in the common dung-heap.

It is, however, from the larger animals that the farmer derives the principal part of the dung that is made use of as manure, in the cultivation and improvement of land. The dung of such horses as are highly fed being found, as has been already seen, to be much more valuable for the general purposes of agriculture, and some uses in horticulture, than that which is made by horses when fed with hay or grass only. Where the animals are kept in the latter way, it is probably not so good as that of well-fed cows and neat cattle in general, as in these it may, perhaps, become more animalized from the circumstance of their food being more intimately blended with the saliva, or other juices, during the ruminant state of feeding in such animals. The dung of horses is, however, in common much more disposed to the process of putrefaction, and cause more heat, than that of cows and other neat cattle; and indeed these are the chief distinguishing circumstances between them as manures. The dung of neat cattle may also, on account of its less disposition to run into the state of putrefaction, contribute more of the earthy material to the land on which it is applied. Hence, probably, its superior utility on the leaner and poorer or thinner sorts of soil. The dung and urine of animals when newly voided are not, except when the animals are morbid, in a putrescent condition, the length of time in which they remain in their bodies being too short for its fully taking place; but some degree of, or tendency to, putridity is constantly necessary to their discharge.

From the experiments that have been made with the dung of sheep, it is evident that it is equally valuable with that of many other animals that feed in the same way, but agriculturists have not yet turned their attention sufficiently to the means of collecting and preserving it, so that it may be used alone as a manure. The method by which it is at present applied to land is by folding the animals upon it, under which method of management, on many soils, a great part of the advantage must be derived from the operation or action of the ammonia of their urine upon the vegetable matters contained in them, as well as from the consolidation produced by their treading. It is well known that the urine and dung of sheep want no fermentation previous to its being applied to the land; the sooner therefore the seed is sown after folding, the greater is the effect.

Vegetable, as well as animal substances, when deprived of their vital principle or life, are soon rendered fit, by the separation, reduction, and ultimate decomposition, of their constituent principles, for the nourishment and support of new plants. This process is greatly promoted, in all kinds of substances, by the materials being exposed to the free influence or agency of atmospheric air, moisture, and a middling degree of heat; various matters are set at liberty, by which different new combinations take place, that are capable of promoting vegetation in different degrees, and upon which their utility as manures, perhaps, chiefly depends. The stages of this decomposition have generally been supposed to regularly succeed one another, from that which is productive of sweetness, through the vinous and acetous, to that which is the ultimate result of putrefaction. Different sorts and parts of organised matters, when dead,

undergo many different sorts of chemical changes, which are different according to the degrees of heat, the quantity of water, and of air, to which they are exposed.

In the vinous fermentation or process which commences after the saccharine, carbon becomes united with pure air in a large proportion; and it is probable that, at the moment of their combination, while they are in the form of a liquid, and before they assume the gaseous state, they may be taken up by the roots of vegetables.

The substances of the vegetable kind that may be advantageously converted into manure are so extremely numerous, that it is impossible within our limits to describe them. All kinds of green vegetable productions may be employed in this way; such as the luxuriant weeds of rivers, lakes, ponds, and ditches; fern, and the refuse of different kinds of garden vegetables. Where green materials of this nature are made use of, they should always be cut down while in their juicy state, just before their flowers begin to appear, in order that they may be in the most suitable condition for becoming quickly putrid, and to prevent the injury that might otherwise be sustained from the vegetation of their seeds. They are afterwards to be collected into heaps of a moderate size, and their putrefaction promoted by their being thrown together as lightly as possible, and the occasional sprinkling of them with water, if the season be hot and dry; and as lime is found, when applied to vegetables in their green moist state, to disengage from them both hydrogen and azote, by the combination of which volatile alkali is produced, it may be advantageous to blend a portion of lime at first with the heaps, and afterwards add a suitable quantity of peat earth, or good vegetable mould, for the alkali thus formed to act upon. By this method, the quantity of manure from such substances may be greatly augmented, and rendered more valuable. But when dry materials, such as hay, straw of different kinds, fern, and rushes, such additions cannot be had recourse to with equal success, unless where much of the dung and urine of animals have been incorporated with them; but their resolution and decay may be greatly promoted by their being kept in a state of moisture, without the water being suffered to stagnate upon them, and by their not being permitted to be trodden down too much by cattle, or other means, in the farm yards.

Another beneficial means of vegetable manure, which is yet far from being sufficiently practised, is that of providing full crops of succulent green vegetables, such as clover, buck-wheat, tares, vetches, spurry, pease, beans, turnips, and many other similar plants, to be turned down by the plough, in order that they may undergo the putrefactive process under the ground, and by that means be converted into manure, and supply the nutrition of plants.

Sea-weed is another vegetable production which is capable of being employed as a manure with great advantage, and should never be neglected where it is within the reach of the farmer. In some places it is the practice to spread it upon the lands as soon as possible after being cut from the verges of the rocks on the different sea coasts, or collected after

being left by the tides, and to plough it in: where this method is adopted, as little time as possible should be suffered to elapse after the cutting or collecting of the weed, before it is ploughed down; for as the plant in its green or succulent state readily decays and becomes putrid, if there be any considerable delay in the performance of the business, especially when the weather is hot, much of its valuable properties as a manure is dissipated, and carried away by means of evaporation.

Bark, which has been made use of for the purpose of tanning leather, may likewise be employed as a manure: when used in this way it should be collected into moderate sized heaps, before it has become dry by too much exposure to the heat of the sun and wind; and then by having a quantity of lime mingled with it, and being kept slightly moistened with water, its putrefaction and decay may be greatly promoted.

The mud taken from the bottom of rivers, ponds, and other places where water has stagnated for some length of time, fresh or maiden earth, and the scourings of old ditches, are substances that may frequently be employed with advantage as manures, being principally composed of the recrement of decayed vegetable matters. They should not, however, be put upon grounds, especially those under grass, until they have been reduced into a considerable degree of fineness, by means of frequent turning over, and the mixing of a portion of lime, rotten dung, or other materials of the same kind, with them, in order to promote and render the decay of the more solid parts more full and complete.

Substances of the calcareous kind, which are to be considered under this head, produce effects more or less powerful in promoting the growth of vegetable crops, in some measure, according to the state and quantity in which they are applied, the nature of the soils on which they are employed, and the properties of the matters with which they are combined.

Substances that contain much saline matter in combination with their earthy and other ingredients, are found, in many instances, when properly employed as manures, to contribute greatly to the support of vegetation. The materials principally made use of in this way are the refuse of different manufactures, such as bleaching and soap-boiling, where they can be procured in sufficient quantities, as in the vicinity of large towns, and where such manufactures are carried on in an extensive manner; the ashes remaining after the combustion or burning of various green vegetable matters, wood, pit-coal, peat, &c. and some other substances, such as soot and sea-salt.

It is most probably to the different alkaline principles contained in these substances, from the great facility and power which they possess of acting upon and dissolving the parts of animal and vegetable matters, especially such of the latter kind as have been rendered insoluble by the absorption of the oxygen, or pure air of the atmosphere, from long or frequent exposure to it, that their beneficial effects as manures are chiefly to be ascribed.

But these substances, besides their forming in the soils, or the earthy materials with which they are mixed, such compounds as are beneficial in promoting the growth of vegetables may be useful in many cases when pro-

perly applied, and used in sufficient quantity, in correcting acidity, in altering the state or condition of the lands, as by the taking away of moisture from the surface where it prevails in an over-proportion in meadows and pastures, and thereby supports crops of coarse vegetables, and by rendering the texture of such grounds as are under the plough more open and friable, consequently more suitable for the reception of the roots of corn crops.

It is evident, from what has been already observed on the nature of the different substances that are capable of being made use of as manures, that they may frequently be mixed and blended with each other, or with substances of other kinds, and by such means be not only considerably increased in quantity, but in many cases rendered more effectual and more suitable for application than in their simple states; but at the same time, that some of them may be mixed and incorporated in this way with much more advantage than others; for though the general experience of farmers has fully shewn the great importance and utility of employing compound manures, or composts, little attention has till lately been paid to the compounding or mixing together of such substances as are, from the principles which they originally contain, or which are formed from them in the changes which they undergo in the different stages of their decomposition, adapted to act in the most suitable manner for producing such combinations or alterations in the materials as are capable of being beneficial in the promotion of vegetation when they are employed as manures.

Farm-yard manure, which is the most general application of any, from its being formed by the decay of various kinds of vegetable matters, such as hay, straw, fern, and many other materials of a similar nature, with which the dung and urine of animals is incorporated and combined, must be considered as a compound substance. And from the large proportion in which such vegetable productions enter into its composition, and the quantity of earthy materials that is in most cases, especially where the management is upon a judicious plan, added by the laying of suitable bottoms, it is not so frequently necessary to be blended with other substances that are usually employed in forming composts. But from most of the vegetable materials that constitute the chief part of this sort of manure, being made use of in a dry and hard state, they do not so quickly ferment or run into the state of decay, notwithstanding the proportion of animalized matters that may be mixed with them; it therefore becomes an useful practice to turn them over, by which their complete putrefaction may not only be promoted, but the different materials be more minutely blended together, on both which accounts they may become more useful when applied as manure upon land. In the forming of this manure, care should also be constantly taken that the heaps be so situated as that they may not become too dry, or too much soaked in water, as in either case they must be greatly injured. Whenever it may be requisite to incorporate any earthy material with this sort of manure, the agricultor should always carefully attend to the state or richness in which it may exist in the yard, and proportion such additions accordingly. It will, however, never demand nearly

so large a proportion, as such manures as consist almost wholly of animal matters.

Where animal matters are collected and thrown together in any quantity, there can be little doubt but that a great increase of good manure may be provided by mixing with them, as has been already observed, rich surface-mould, peat-earth, or the scrapings of old ditches and roads; as by such a practice the ammonia formed during the decomposition of the animal substances is prevented from escaping, as would otherwise be the case, which, by combining with and acting upon the earthy materials, quickly renders them proper for the purposes of manure. As substances of the animal kind have been shewn to run very rapidly into the state of putrefaction, they may frequently be incorporated with such vegetable materials as are little disposed, or with difficulty made, to rot or become putrid, and by such means useful composts be more expeditiously formed. In making use of such earthy substances as have been mentioned, it may be of much advantage to have them exposed to the influence of the atmosphere for a considerable length of time, frequently turning them over, before they are mixed with the manures, as by such means they become in a more pulverized state, and are capable of being more intimately blended with such materials, and afterwards spread over the land with much greater equality, a circumstance upon which their effects very much depend. If, in performing this business, the earthy substances be formed into a sort of ridge, about five or six feet in height, and nearly the same breadth in the bottom, they will be in the most proper situation for being united with dung, or other matters that may be employed.

In the application of manure to land, several circumstances are necessary to be considered, such as the state or condition of the substances which are to be made use of, the nature of the soils on which they are to be laid, the kind of crop that is to be promoted by them, and the season in which they are put into or upon the ground.

As we have already seen that changes are continually taking place from the moment the materials of the dung-heap are thrown together, to the period in which they are reduced into a black carbonic earthy matter; and that in most of the different stages through which they pass in this process of decomposition, such substances are formed as are capable of contributing to the nutrition and support of vegetable crops; it seems probable, that in cases where manures are to be turned into the ground, and such crops cultivated as require a supply of nourishment for a considerable length of time, they should be employed in their long or more imperfectly reduced states, as by the heat which is evolved in the commencement of their dissolution, the process of early vegetation may be greatly promoted, and their gradual decomposition and decay afterwards, under the ground, afford a more durable and regular supply of nutrient materials, and thereby contribute more effectually to the growth of the crops; but that where they are to be buried in, or applied to, the surface of the soil, and intended merely for the benefit and support of such crops as are of short duration, or quickly arrive at their full growth, they may be more advantageously made use of after they have

seen more fully and completely reduced, as in this state the manure is, in the case of grass lands, not only capable of being spread out in a more regular and uniform manner, by which it becomes more evenly as well as more generally carried down to the roots of the plants by rains, but it is in the most suitable condition for allowing the young plants the means of springing up with facility, and at the same time, whether used under or upon the soil, of affording the crops that abundant supply of nourishment which is necessary to their speedy growth and great luxuriance, and by these means to contribute the most perfectly to the promotion of their increase.

And as in the slow and gradual decomposition of the materials which are made use of for manures, when slightly deposited beneath the soil, there is much less waste of heat and those elastic matters which contribute so greatly to the support of vegetation, than where they are made to undergo the various processes of dissolution in large masses, as in dung heaps, they may probably sometimes on that account be most advantageously employed in this state.

On this principle too the ploughing down of fresh vegetable crops, in many cases, in their most succulent states, may be a more economical as well as more beneficial practice; especially in such light and dry kinds of soil as will more readily admit of their gradual putrefaction and decay, than to cut and take them off for the purpose of being by other means converted into manure. It seems likewise probable, on the same grounds, that for the production of crops of bulbous-rooted vegetables, on the more stiff and tenacious soils, the matters made use of as manures may be employed with the greatest advantage, when put into the earth before they have undergone any great degree of decay by means of putrefaction, as in this way there is no waste, the whole being ultimately converted and applied, though more slowly, to the support of the crops.

As to the season in which manures may be put into the soil, or spread out upon its surface, with the greatest benefit and advantage, though in practice it must, in some measure, depend on the state of the land and the convenience of the farmer, it should, in cases where they are buried in the ground, be as nearly as possible to the periods in which the seeds or roots which they are designed to support, are sown or placed in the earth; and in the latter case, or where they are to be laid upon the surface of the land, it ought to be just before the crops of grass, or other vegetables, begin naturally to spring or shoot forth.

And by the application of such manures as are employed in the way of top-dressings in the beginning of the spring, they are laid on in the most favourable period for affording their nutritious principles, and for their being drank up by the roots of plants, consequently become useful at the time they are most wanted for the promotion of the crops, and the great waste which must otherwise be caused, either by the excessive falls of rains and floods in the winter season, washing down much of the valuable properties into the adjoining rivers and ditches, or the evaporation of their more volatile or elastic matters by means of the summer heats, is most effectually guarded against and prevented.

On all these accounts, therefore, farmers should contrive as much as possible to apply the manures, intended as top-dressings to grass lands, as early in the spring as it can be conveniently done, which may be easily managed on those that are dry, and on such as are inclined to be wet and poachy, it may probably be greatly facilitated by having small light carts constructed for the purpose, and placed on broad cylinders as wheels.

In the application of manures to lands under tillage, as well as those in the state of grass there are a few other circumstances that require the attention of cultivators; such as the depth they may be deposited in the soil, the modes of putting them upon the ground, and the most economical methods of employing them.

In respect to the advantage of using one sort of manure in preference to another, it may be observed, that as animal matters are found in general to undergo more speedily the process of putrefaction or decomposition, than those of the vegetable kind, and as in most instances they afford those mucilaginous and elastic principles that contribute so largely to the support of vegetable life in greater proportions; such manures as are either wholly or in a great measure composed of them, must be the most beneficially employed, where quick and abundant supplies of nourishment are required, as in the growth of all the more gross and luxuriant crops, whether of grain, plants, or grasses; and that as those vegetable substances which contain saccharine, farinaceous, oily, saline, or mucilaginous principles in the largest quantities are ascertained from experience to proceed the most readily into the state of dissolution or decay, and consequently to afford more fully and more expeditiously the nutrient food of new plants, where manures are principally formed from them, they should be preferred to such as have been made from the harder and more ligneous vegetable substances; that contain such properties in scarcely any, or much smaller degrees, for all the purposes of agriculture.

Of the natural spontaneous grasses. Having thus stated the nature and principles of the various soils which are met with on the surface of the earth, and shewn the different modes of improving the same, it becomes us, in the next place, to speak of the best natural productions thereof, especially of the gramina kind; that from thence the agricultor may make his selection of such land as may be most profitable.

In our meadow and pasture lands we find a great variety of grasses, of which some are far more valuable than others; to know the good from those which are indifferent becomes the interest of the farmer; we therefore give him the characters (accompanied with figures. See plates I. and II.) of the most valuable, so classed in our catalogue as they stand in precedence of quality one to another.

1. Great smooth stalked meadow grass—*Poa pratensis*.
2. Hard fescue grass—*Festuca duriusculo*.
3. Meadow fesc. grass—*Festuca pratensis*.
4. Ray grass—*Lolium perenne*.
5. Meadow fox-tail grass—*Alopecurus pratensis*.
6. Sheep's fescue grass—*Festuca ovina*.
7. Rough stalked meadow grass—*Poa trivialis*.

8. Marsh meadow grass—*Poa palustris*.
9. Compressed meadow grass—*Poa compressa*.

10. Crested dogs' tail grass—*Cynosurus cristatus*.

11. Knotty cats' tail grass—*Phleum nodosum*.

12. Sweet scented spring grass—*Anthoxanthum odoratum*.

Great or smooth-stalked meadow grass.

This grass is considered as the best of all we have; it is early in its foliage, makes the best hay, affords the richest pasture, all sorts of cattle are fond of it, it is in all our meadows, and will continue in the same land much longer than any other grass.

Hard fescue. This is an early and productive grass, with fine foliage, which grows well on downs and rich meadows. It is well adapted for being combined with other grasses in forming sheep pastures, and stands high in esteem as a very good hay grass.

Meadow fescue grass. This is a grass that comes near in its appearance to ray grass, but to which it seems greatly superior, as being larger, and more productive of foliage. It is strictly perennial and hardy, thriving well in most soils, growing in all situations; and it abounds in the best meadows, in the best hay districts; is sweet, luxuriant, and quick of growth, affording rich pasture, and making good hay. In short, it seems well calculated to supply the defects of ray grass. Besides, it has the quality of producing more seeds than most of the other sorts of grasses, which are easily gathered, and grow readily.

Ray or rye grass. This is a sort of grass that has been much in cultivation, but is deficient in some of the properties necessary for meadow or pasture lands. In rich moist meadows its foliage is abundant; and it seems probable that it is highly acceptable and nutritious in feeding cattle; its foliage is of rapid growth, and flowering stems continually shooting forth. It is best adapted to the loamy and sandy descriptions of soils; but it will succeed on any except stiff clay, and even on that it may be grown.

On converting ray grass into hay, it is necessary to cut it at a period previous to its being so ripe as to have perfected its seed, and changed to a yellow colour; for in this case a great part of the juices of the plant, which constitute a principal part of the nutriment it is to afford, will be converted into a species of straw, and its nutritive properties be proportionably diminished.

Meadow fox-tail grass. It is in some measure distinguished by the largeness of its foliage, which is rather coarse, and by its producing a soft spike on a long stalk, early in May. If it be mown early, just as it comes into bloom, the hay will not be coarse. It shoots very rapidly after mowing, and produces a plentiful aftermath.

Sheep's fescue. This grass is praise-worthy both for the purposes of pasture and hay; sheep and other sorts of stock are fond of it, and are soon rendered fat in pastures where it prevails, giving to mutton a sweet delicious flavour.

Rough-stalked meadow grass. It delights in moisture, and situations that are sheltered; on which account, though there are few more productive, or better adapted for the purpose of hay or pasturage, it is tender, and liable to be injured by severe cold or drought;

and in moist rich ground it has been observed to grow tall, while in poor land it has been found equally diminutive. It is a grass well adapted to good, sound, moist loams. The produce is admirable for the feeding of all sorts of cattle.

Marsh meadow grass. This is a fine exuberant grass, and one of the best dairy grasses we have. It grows in all our rich marshes, which are subject to be flooded in the winter; generally four feet high. Its panick, when full-blown, is wonderfully fine and flowing.

Compressed meadow grass. This is an excellent grass for parks and sheep walks, deer and sheep being fond of it; and as it is a dwarf grass, the blades seldom exceeding two inches, it makes a fine turf, and renders the flesh of the animals short, and sweet flavoured.

Crested dog's tail grass. This is a grass that is a favourite and wholesome food for sheep. It grows best in dry pastoral lands, and will not thrive in meadows that are very moist. It abounds greatly in the best pastures, and is a blade grass that shoots up the first after the land has been mown; its thickest tufts afford much food for sheep in the time of snow and severe weather in the winter season. From the rapidity of its growth it may be apt to get coarse, if not cut down more quickly than is often the case.

Knotty cat's tail grass. It is a fine exuberant grass, very fit for dairy pastures and for cow-hay. It produces much rich milk, and kine are fond of it.

Sweet-scented vernal grass. This is a sort of grass that comes early into blossom; and is also valuable for its readiness to grow in most kinds of soil and situation, but in point of crop it is not so productive as some others; and it is well known to be the only grass of this climate which is odoriferous; the agreeable scent of new-made hay being produced almost entirely by it; and the green leaves, when bruised, readily impart this odour to the fingers, by which means the foliage may constantly be known.

Cultivation of grass lands. Lands in the state of grass must obviously be applied to different purposes, according to their nature, situation, and other circumstances. Those which are of the more moist kinds, whether from the nature of the soil or the peculiarity of situation, are for the most part kept under the scythe; while those of the contrary description, that are situated at a greater height, and of course, in most cases, possess a greater degree of firmness, are in general appropriated to the purpose of pasturage: though, in particular situations, where grass land is scarce, and consequently of great value, it is good management to convert them occasionally to the purpose of hay.

Meadow lands, from their being situated in the hollows and sloping sides of the valleys, where the staple and depth of soil of the lands have for a long time been continually increasing by the deposition of various sorts of vegetable and other matters brought down from the higher grounds, are, however, in general, in a considerably greater state of fertility, and evidently better fitted for the permanent production of grass than those from which they have derived their richness.

Management of meadow lands. From the greater retention of moisture in the vale land, in consequence of their situation, and the depth of vegetable matter, they are liable to

throw up coarse herbage in many cases, more drainage, as well as other management, is necessary to bring them into the proper condition for the growth of good herbage, than is requisite in the hay grounds in the more elevated places. And by a more particular attention in these respects they would, in many instances, be rendered a vast deal more productive than they are at present, and at the same time afford a much better herbage. They would also admit stock upon them a much greater length of time, both in the autumn and spring seasons.

The most proper season for surface-draining grass lands is in the autumn, when they are somewhat firm and dry, as in the early spring months such lands are too full of moisture. The grips, or small open drains, should be cut obliquely, in the most suitable directions for conveying off the superficial stagnant water, the materials taken out being wholly removed. Much of this sort of draining may be performed at a small expense, and the beneficial effects be very considerable.

Meadow lands also demand much more attention in their management than those which are fed by cattle. In all cases stock should be turned upon the lands, and manures applied with much care, and only when the land is in such a state of dryness as not to be injured by the poaching in or breaking of the sward.

It must be evident, that the breaking of the surface, texture, or sward of grass lands must in all cases be prejudicial, not only by the destruction of plants, which is thereby immediately produced, but also by the retention and stagnation of water upon them in the holes and depressions from small portions of the turf being forced in.

The most proper periods of shutting up such grass lands as are designed for hay must, like those of eating them down in the autumn by stock, depend on various circumstances that can only suit the particular cases. In general, however, it is the best practice not to delay it too long. When the lands are not eaten at all in the spring by cattle, after the sheep have been removed, about the middle of February, nothing further should be allowed to enter the meadows; by which means a quick vegetation is secured, as well as a more plentiful crop and a more early hay harvest. And in other cases it should seldom much exceed the middle of March, as when eaten much later, there is not time for the grass to produce a full crop before the commencement of the hay season; of course the farmer sustains more loss than can be repaid by any advantage in the additional feeding he may obtain. This is, therefore, the best practice where the view of the farmer is hay; and it should be particularly adopted and attended to in cow farms, where it is of much importance to cut early, to secure hay of a fine, grassy quality, for the purpose of producing large supplies of milk.

After the meadows or other grass lands have had the cattle and other sorts of live stock removed from them in the early spring months, and been shut up for hay, they should be prepared for the scythe, by having all sorts of obstructions picked up and removed. This work should always be executed as soon as possible, before the grass begins to spring up too much and conceal

them, as it is difficult to perform the business effectually afterwards.

It is an excellent practice to have all sorts of coarse plants of the aquatic and other kinds, such as rushes, fern, docks, thistles, and various others, effectually drawn up and eradicated both from the hedge-rows and other parts of the fields, in order to prevent their running up to seed and disseminating themselves over the lands.

Mowing of hay lands. In the cutting of grass crops for the purpose of being converted into hay, it is necessary that they be in the most suitable states of growth and maturity for affording the best and most nutritious fodder. With this view, it would seem that they should neither be cut at too early a period, nor suffered to stand too long; as in the former case there will be considerable loss in the drying, from the produce being in so soft and green a condition, and in the latter from a large proportion of the nourishing properties being expended. It is probable, therefore, that grass, when mown before it becomes in full flower, while the rich saccharine juice is in part retained at the joints of the flower-stems, is in the most proper condition for being cut down, as at that period it must contain the largest proportion of nutritious material, but which then begins to be absorbed and taken up in proportion as the flowers expand and the seeds ripen.

But there are other circumstances besides those of ripeness to be attended to in determining the period of cutting crops of grass; as in some cases, where they are thick upon the ground, the bottom parts become of a yellow colour before the flowering fully takes place: under such circumstances, it will always be the most advisable practice to mow as soon as the weather will possibly admit; for if this is neglected there will be great danger of its rotting, or at any rate of its acquiring a disagreeable flavour, and of becoming of but little value. Where grass is very tall, as is often the case in moist meadows, it is liable to fall down and lodge, by which the same effects are produced. In this case also the mowing should be performed as soon as possible.

In the operation of mowing, the chief art consists in cutting the crop as close to the surface of the ground as possible, and perfectly level, pointing the swaths well out, so as to leave scarcely any ridges under them.

Hay-making. The great art in converting grass into hay consists in rendering it sufficiently dry to prevent its fermentation taking on too great a degree of heat in the stack or mow, and at the same time preserving a large proportion of the natural juice of the plants. Where this medium can be attained with the most exactness, the best and most nutritious hay will be produced.

In the making of hay, some attention should be paid to the quality of the soil and the kind of herbage growing upon it. The hard benty hay of a poor soil is in little or no danger of heating too much in the stack; it should, therefore, be put very early together, in order to promote a considerable sweating, as the only means of imparting a flavour to it, which will make it agreeable to horses and lean cattle, as it will be nearly unfit for every other sort of stock. It is the succulent herbage of rich land, or land highly manured,

that is most likely to generate too great a degree of heat; of course grass from such land should have more time allowed in making it into hay. In moderately hot seasons the proper point of drying may be easily judged of; but when they are very hot and scorching it is easy to be mistaken; as in such weather the grass becomes crisp, rustles, and handles like hay, before the moisture or sap is sufficiently dissipated for it to be in a state fit to be laid up in large stacks. If that, however, be done when it is thus insufficiently made, it mostly heats too much, becoming mow-burnt in some cases.

The art of hay-making much depends in the due observance of the following rules, as nearly as circumstances will admit.

In the first day's process all the grass mown before nine o'clock in the morning must be tedded or spread out, great care being taken to shake it so as to leave it free from lumps, and to strew it evenly over the whole surface of the ground. It is soon afterwards turned, with an equal degree of care and attention; and if the number of hands be sufficient, they turn the whole again, or at least as much of it as they can before one o'clock. It is then raked into what are termed single windrows, or so as that each person may form a row at about three feet distance; and the last operation of the day is to put it up into grass cocks. The business of the succeeding day commences with the process of tedding all the grass that was mown the first day after nine o'clock, and all that was mown the second day before the same hour. The grass-cocks are then well shaken out into separate plats of five or six yards in breadth. The plats are next turned, and after that, the grass that was tedded in the first part of the morning once or twice, in the same manner as described in the first day. This business should all be performed before one o'clock, that the whole may lie to dry while the people are at dinner. After this the first thing is to rake the plats into double windrows, which is done by every two persons raking the hay in opposite directions or towards each other, forming a row between them of double the size of the single windrows, each being about six or eight feet distant from the other. They afterwards rake the grass tedded thus into single windrows; then put the double windrows into bastard cocks; and conclude by putting the single windrows into grass-cocks. The labour of the third day is begun by first tedding and spreading out the grass mown and not spread the preceding day, as well as that mown in the early part of the day, and then the grass-cocks are thrown out into plats as before, and the bastard cocks into plats of less extent. These narrow plats, though last spread out, are first turned, then those which were in grass-cocks; and lastly the grass is turned once or twice before one o'clock. When the weather has been sunny and fine, the hay which was last night in bastard cocks will this afternoon be in a proper state to be carried, as in fine seasons it may mostly be performed on the third day; but when the weather has been cool and cloudy, no part of it probably will be fit to carry. In that case, the first business after dinner is to rake that which was in grass-cocks last night into double windrows; then the grass which was this morning spread from the swaths into single windrows. After this the hay which was last night in bastard

cocks is made up into full sized cocks, and care taken to rake the hay up clean, and also to put the rakings upon the top of each cock. And lastly, the double windrows are put up into bastard cocks and the single ones into grass-cocks, as in the preceding days. On the fourth day the great cocks just described are mostly carried before dinner. The other operations are similar to those of the former days, and proceed in the same order, continuing them daily until the whole is finished.

During the whole course of hay-making the grass should, as much as possible, be protected both in the day and night against rain and dew, by cocking.

The preserving hay of a proper green colour is a circumstance of some importance. In order to effect it, the bastard cocks, previous to their being carried, should be put up in the heat of the day, and remain in that condition till the following morning, when they must be turned and opened so as to dispel any damp that might induce it to heat in the stack, and in that way spoil the colour. The acquisition of a lightish brown colour in the stack is not found injurious to hay, but where it becomes of a dark brown from too much heat, it is said to weaken and relax horses that are fed upon it by its powerful diuretic quality. It is of course of inferior value for that purpose, but not the worse for fattening cattle with.

For the purpose of facilitating the business of getting the hay together in bad showery seasons, hay-sweeps have been constructed.

A contrivance of the first sort has been invented, and described in vol. xiv. of the Transactions of the Society for the Encouragement of Arts, Manufactures, &c. It is so constructed as to be drawn by four horses in pairs, but smaller ones might be made to be drawn by two, and is managed by two boys, one of whom drives each pair of horses, being mounted on one of them. Where the ground is level, little more will be necessary in order to assist the machine, than merely to break and turn up the rows of hay in different places. In catching or showery weather, such a machine may be particularly useful, in getting a field of hay, nearly dry, into large heaps in different parts of the field, whence it may be made into large cocks of half a ton or more each, with the utmost facility.

Stacking and thatching hay. The form of the hay stack is not a matter of much consequence, the long square, or oblong shapes are the most safe and convenient, especially when not too broad, as they admit the air the most fully. But the circular form for farm use, where straw is scarce, may be the most advantageous in the economy of straw in thatching.

The size of the staddle or stack bottom should be proportioned to the quantity of hay, but it is better not to have the stacks too large; 24 feet by 14 or 15 is for most occasions a good size.

The business of stacking hay is best performed, if possible, while there is a full sun, as by such means it is much improved. It is necessary to have a person that understands the art of setting up stacks, and a sufficient number of helpers to assist in spreading the hay and treading it well down. In building, the middle of the stack should always be well kept up, something higher than the sides. In this district, where work of this sort is well executed; at leisure times, during the whole period the

stack is building, the men are employed in pulling the sides and ends into proper form.

After the work of stacking has been completed, and the stack is pulled and topped up, it is left till it has sweated, and is perfectly settled, which is mostly the case in a week or ten days: the roof should then be well covered by a good coat of thatch. The roof should be dry when the thatch is put on, to prevent the hay from becoming mouldy. It is of great consequence that this sort of work be well performed.

It is a point not perfectly decided among agriculturists, whether hay keeps better in stacks in the open air or in barns for the purpose. It is the opinion of most farmers that the first mode has the advantage in so far as respects the quality of the hay.

After-grass. Where after-grass is fed off by stock, there is much difference of opinion in regard to the most proper periods of turning in the animals. Some have contended that it is the best practice to let them into the field before the young grass has attained any very great head; while others maintain the opposite doctrine, and think it the best method to allow the grass to get up to a full bite before the stock is turned upon the land. Both endeavour to support their opinions by experience. But as they cannot be both of them true, it is probable that the extremes of each are to be avoided; and that, as in many other matters, the truth may lie in the middle. This is indeed equally supported by fact and the observation of the most intelligent managers; as when the cattle are turned in too early there is not a sufficient bite to keep up the condition of the animals; while in the contrary extreme, the stock so soon fill themselves, that much of it is trodden down and wasted afterwards in their roaming about the fields to pick the sweetest morsels.

Where much stock is turned upon after grass in a full state of growth, there cannot be any doubt but that much loss must, as has been just observed, be sustained by the treading down and rendering the grass unfit for being eaten off. It is therefore perhaps only by beginning the pasturage of after-grass when in the middle state of growth that it can be consumed to the best advantage, and without loss in either of the ways that have been just noticed.

In the stocking of after-grass, some attention is necessary not to have too great a number of animals on a given proportion of land. One cow to the acre on well-grown after-grass is an ample stock. Good grass-land may, however, admit something more.

Management of pasture lands. Having explained the different methods of management that seem necessary to the cultivation of those sorts of grass lands that are chiefly applied to the purpose of producing hay, we shall now describe the modes of practice which appear requisite in such as are almost wholly appropriated to the support and fattening of live stock.

The grounds that are the most perfectly adapted to this use are, all those which have a considerable depth of good mould, and at the same time that they afford a good herbage, are so dry in their nature as to admit the animals to feed upon them at almost all seasons without injury by poaching. Coarse rushy lands may, however, in many cases be converted into good pastures, by proper at-

tention in draining, and cutting over the rushes in the early part of the spring, and about Midsummer, as by these means the plants decay, the young shoots being afterwards eaten by young stock, and the good grass plants allowed to flourish.

Pasture lands should likewise, as much as possible, possess properties in the nature of their grasses that are the most advantageous for the particular method of management under which they are to be conducted. In this view, some may be more adapted to the producing of milk or butter, others of cheese, and others again of feeding or fattening animals. It is in some measure on this account, as well as that of local convenience, that different modes of management are employed on grass lands.

The difference of situation in pasture lands has likewise much influence in directing the uses to which they may be applied with the greatest benefit. The higher or more elevated grounds being in general more proper for sheep, while those of the lower and more inclosed kinds are mostly better suited for the purpose of neat cattle or other animals under the fattening system.

Pastures, when not well attended to, are frequently prevented from being properly fed, by various kinds of low shrubby plants, such as those of the alder, brier, broom, furze, and other sorts that shoot out upon the surface; these which should always be extirpated as soon as the business can be conveniently done; as by their remaining upon and shading the ground they render the herbage sour, and improper for the food of cattle. This sort of work may be performed by cutting them closely down as they rise in the early spring months; but a better practice is to dig them completely out.

Where pastures are productive in grasses of the more sharp coarse bladed kinds which rise into tufts or tussocks, and which are known to agricultors under the titles of pink or carnation grasses, it is a certain indication that the soil is too retentive of moisture, and stands in need of draining.

The improvement of the fertility of pasture grounds may be effected in different ways, as either by the direct application of manure in its natural state, such as that of rotten dung, lime, marl, or in that of earthy compost, occasionally, over their surfaces in a thin even manner; or indirectly by the folding or confining of sheep upon the land during the time they consume other sorts of green food, such as turnips, &c. The latter mode is unquestionably the most advantageous and convenient, as it is in but very few situations that the former can be practised without robbing the arable or hay lands of their property.

In explaining the methods of management that are necessary in the cultivation of arable lands, in order to afford a suitable state of soil and nourishment for the growth of grain or other crops, it will be proper to consider them as relating to grounds that have not yet been brought under the plough, and such as have been already in the state of tillage.

Removing obstructions to tillage. In the first place, the removing of stones, the eradicating of wood, the destruction of different sorts of plants, and the removal of such degrees of wetness as may be injurious, before the business of ploughing or loosening the

mould of the soil can be properly carried on. The stones that oppose obstruction, in this view, are principally either such as are met with in a loose state in the ground on its being ploughed, or such as are fixed in the soil, and incapable of being removed without much labour and difficulty. Some of these last are often of such a size as to present themselves upon the surface, and cause much land to be lost, by their not permitting the plough to come near them. Those which are concealed below the surface are, however, the most detrimental, as the implements are frequently destroyed, and much inconvenience experienced from them, before they can be perceived by the ploughman, though he may be perfectly attentive to the circumstance.

In all cases, land should be as much as possible cleared from such stones as retard or prevent the operation of the plough before the business of tillage be undertaken; as without due attention in this respect considerable loss may be sustained by the breaking of implements, and the great delay that must take place in the work.

In the clearing of lands from wood, different methods must be pursued, according to the nature of the wood with which they are covered. Where there are large trees of the timber kind, they should be completely grubbed up at a proper season of the year, care being taken that the roots be as much as possible removed.

In cases where broom, furze, brambles, or thorn shrubs, have become of considerable size, the general method of proceeding is to cut them down as close as possible to the surface of the ground, and afterwards to dig round, and grub up the roots in the manner that the larger trees are cleared. With furze it is sometimes customary to set fire to them, in order to uncover their stems before any attempt is made to grub them up; but this is a practice that ought to be as much as possible avoided, from the danger that may attend it, and the loss of the furze, as well as a large portion of the valuable vegetable matter accumulated in many cases beneath them.

As it has been found from experience, that such lands as have been attempted to be cleared from brushy plants of this kind, especially those of broom and furze, are extremely liable, from the roots and seeds that may be left in the soil, to have them coming up again in great abundance after they have been laid down to grass; it should be a practice to keep lands that are much disposed to their production in the state of tillage for such a length of time as may be fully sufficient, by the various means of cultivation, and the application and blending of lime and other suitable manures with them, to have them as completely removed as possible; and that when they are restored to the state of grass, to have them pastured, as much as can be conveniently done, with sheep.

Heathy lands should be cut as close to the surface of the ground as it can be conveniently done; and lime, in its caustic state, should be applied in large proportions.

When this sort of ground has been broken down and pulverised as much as possible by the operations of ploughing and harrowing, it should always, where not too stiff, be sown with some sort of close, luxuriant, green crop, such as turnips, peas, and tares, that may be fed off by sheep; but where it has a sour qua-

lity, and is more stiff, clayey, and adhesive, those plants that strike more deeply into the soil, as beans, rye, and oats of the grey kind. In many cases too, rape, peas, clover, and vetches, will succeed in a very beneficial manner. But as the principal intention in most cases of breaking up this sort of land, is that of bringing it in a cheap and expeditious manner to a suitable condition after a grain crop or two for growing grass, the green crops, of whatever description they may be, should be consumed by animals upon the ground.

And in whatever method such lands may be brought into the state of cultivation, the processes of tillage should not be carried further than the destruction of the heathy or other coarse plants, and the removal of the sour and unfriendly disposition of such soils for the growth of useful vegetable productions. They should be then restored as soon as possible to the state of grass or pasture.

There is another description of land that is frequently to be brought into the state of tillage; this is that of the boggy kind. In these the first thing, after having them well drained by the cutting of proper ditches, which, where they are large, may serve for their inclosure, and by giving the ridges a suitable form in order to aid this, is to pare off and level the surface by means of the spade or plough; such matters as are of little value being deposited in the hollows, while those that are of a good quality may be mixed into a compost with good dung, where it can be procured, or with lime; together with the spare earth taken from the ditches, which should be immediately spread equally over the land, and incorporated, as much as possible with it, by ploughing it up with a very slight or ebb furrow, in order that the uniting materials may not sink too deep for affording due support to the crop, that it may be cultivated. Indeed, though deep ploughing may sometimes be of utility in first opening up these soft soils, it should never be had recourse to when the application of manure is to be made; and on this account also the ploughings after the taking of different green crops should only be slight. It is seldom proper to continue soils of this description for any great length of time in the state of tillage, as from their great moisture, on account of the general flatness of their situation, and their being liable from continued ploughing to become very loose and open, so as not to afford proper nourishment and stability to the roots of the crops, this sort of land will in general be the most advantageous in the state of grass.

The most beneficial sorts of crops for these soils will in general be turnips, rape, or potatoes. The light and drier parts will be the most adapted to potatoes, as their bulbous roots will be there the most able to spread and extend themselves, and consequently produce large crops. These crops will, in the stiffer sorts of these soils, leave the land in a suitable condition for wheat or oats, and in the lighter for barley or rye.

Moss lands, from their being much disposed to the throwing up of grass, are not so proper for the growing of grain crops, but a crop or two may frequently be taken after potatoes or turnips, especially where liming has been performed some length of time. Oats and barley are mostly good crops, but

such land is often too light for wheat. Where barley is employed, grass seeds are frequently sown with it, but it is probably a better practice to put them in separately. On those soils, rye-grass, as well as white and yellow clover, have been found to thrive extremely well, especially where they were in a proper state of preparation for them, as by the growth of potatoe or turnip crops. And though red clover has not always succeeded, it is probable, that in such mosses as are not of the deep kind, it will be found an useful plant. In some districts it has been found that clover may be sown with great advantage immediately after the potatoe crop, when it has been taken off early.

It is evident, from what has been advanced, that as there is much variety in soils of this kind, they will of course require different modes of tillage. Where they are very thin, and deposited upon a loamy or clayey substratum, it may be a good practice to plough so as to bring up a portion of them, by which, and the use of lime, the land may be rendered highly productive.

Ploughing. This, or some other method of loosening and turning up the superior parts of soils, is constantly requisite in order to render them suitable for the reception of the seed or crop that is to be cultivated. It is by means of this kind that a convenient bed for the roots of the young plants, and a proper condition of the land for supplying them with due nourishment, is in a great measure provided, as well as a proper state of dryness in many cases afforded.

There are certain circumstances that constantly demand notice in the practice of ploughing land. In all the stiff, heavy, and more adhesive kinds of soils, that are much disposed to the retention of moisture, whether they be perfectly clayey, or have more of a loamy quality, it should be a common rule never to plough or turn them up when wet in any great degree, except where the nature of the crop requires it. And further, great injury is produced by the treading of the team, as well as a much greater power necessary in performing the operation. But at the same time they should not be permitted to become so dry and hard as to afford too great resistance in that way, before the operation is proceeded upon.

But in the dry, sandy, and probably in some of the more mellow and friable kinds of loamy soils, the business of ploughing, especially for the putting in of the seed, may be performed when they are in a state of considerable moisture, not only without their suffering any inconvenience, or the seed being injured, but often with advantage, as they are liable to part with the watery particles that they contain too readily. On this last account the very dry sorts of sandy land should, whenever the weather is hot and dry, merely be stirred in such way as may be necessary to prevent the growth of weeds, otherwise the great exhalation of moisture in such seasons may render them too dry for the healthy vegetation of the seed or plants that may be sown or set upon them.

In regard to the depth and frequency of ploughing lands, they most constantly depend, in a great measure, upon the qualities and the sorts of crops that are to be grown. But in general the different preparatory ploughings should be deeper than those of

the seed furrow, which ought mostly to be light, and the slice not too much laid over, that the seed, especially where the broad-cast method of sowing is adopted, may be the more perfectly covered.

Upon all light soils it is necessary to preserve, at six or eight inches below the surface, what farmers call a pan; that is, the staple, at that depth, should be kept unbroken; by which means manure will be kept longer on the top: and in dry seasons the less depth the pan has, the less liable the corn will be to burn, provided the pan consists of earth, and not of rock; because the roots of the corn will find more moisture by striking against a body of close earth than they will in a greater depth of hollow earth; as it is evident the former preserves more moisture in dry seasons.

In regard to the frequency of ploughing or turning over ground, in order to prepare and render it suitable for the production of good crops, it is obvious there must be much difference according to the nature and condition of the soil, as well as the kind of crop that is to be grown. The stiff, clayey, loamy, and even chalky soils will, in general, stand in need of more frequent stirring, either by means of the plough, drag, or harrow, in order to separate and break down their tenacious particles, than those of the sandy or gravelly, and more light kinds, in which there is much less adhesion. Besides, where lands, have been in a course of tillage for some length of time, whether they are of a clayey, loamy, or even sandy quality, they may require less frequent stirring than where the contrary is the case. And where the method of putting the seed into the ground by means of drill machines is to be had recourse to, a fine state of tilth will, in general, be indispensably necessary.

The nature of the crop that is to be cultivated must, however, in most cases, direct the number of ploughings that may be necessary, as some demand a much finer state of tillage than others; though in most cases a well-reduced earth is favourable.

In the choice of implements for the performance of this business, the agricultor should be careful that they are well suited to the nature and quality of the land, as it is not possible that any particular sort of plough can be employed with equal facility and advantage on soils of every description. The more stiff and heavy kinds of land will require ploughs of more strength than those of the thin chalky, and a light, sandy, or gravelly nature. The former may mostly be managed in a proper manner by any of the well-constructed kinds of strong ploughs; as the Somerset single-wheel plough, the Hampshire two-wheel plough, and the latter by those of the light sort, as the Rotheram plough, the Norfolk light two-wheeled plough, or the double-furrowed plough. See Plate, Ploughs, &c. But whatever description of plough may be had recourse to, it is a matter of the greatest consequence that it be properly formed and attached to the draught, as where these points are not minutely attended to, there must constantly be a considerable loss in the economy of labour and time, as well as in the compleanness of the work.

HUSK, the same with what botanists call the calyx, or cup of a flower. See CALYX.

HYACINTH, in natural history, a genus of pelucid gems, whose colour is red with an admixture of yellow. See ZIRCON.

HYACINTHUS, a genus of the monogynia order, in the hexandria class of plants, and in the natural method ranking under the 10th order, coronariae. The corolla is campanulated, and there are three melliferous pores at the top of the germen. There are 17 species; of which the most remarkable is the orientalis, or eastern hyacinth. Of this there are a great number of varieties, amounting to some hundreds, each of which differs from the rest in some respect or other.

These plants are cultivated with the greatest success in Holland, whence great numbers are annually imported into Britain. Each variety is by the florists distinguished either by the name of the place where first raised, or the person who raised them, or the names of illustrious personages, as of kings, generals, poets, and celebrated antient historians, gods, goddesses, &c. They are sold by all the seed-dealers. The prices are from 3d. per root to 5l. or 10l. or more; and some varieties are in such high esteem among the florists, that 20l. or 30l. will be given for a single bulb. They are hardy, and will prosper any where, though the fine kinds require a little shelter during the winter. They may be propagated either by seeds or off-sets from the roots.

HYADES, in astronomy, seven stars in the bull's head, famous among the poets for the bringing of rain. The principal of them is in the left eye, called by the Arabs Aldebaran.

HYALITE, in mineralogy, a stone frequently found in trap rocks. It occurs in grains, filaments, and rhomboidal masses. Texture foliate. Fracture uneven, inclining to conchoidal; sometimes opaque; specific gravity 2.11; colour pure white. Infusible 150° Wedgewood, but it yields to soda. According to Mr. Link it is composed of

57 silica
48 alumina
15 lime

90 and a little iron.

HYDATIDES, in medicine, little transparent vesicles or bladders, full of water, sometimes found solitary, and sometimes in clusters, upon the liver, and various other parts, especially in hydropical constitutions. See MEDICINE.

HYDNUM, a genus of the natural order of fungi, in the cryptogamia class of plants. The fungus is echinated or prickly on the under side. There are six species. One of them, named the imbricatum, is a native of Britain, and is found in the woods. It has a convex hat, tiled, standing on a smooth pillar, of a pale flesh-colour, with white prickles. It is eaten in Italy, and is said to be of a very delicate taste.

HYDRA, in astronomy, a southern constellation imagined to represent a water-serpent. The number of stars in this constellation in Ptolemy's catalogue is 25, and in the Britannic catalogue 68.

HYDRA, a genus of vermes zoophyta. The generic character is, animal fixing itself by the base, linear, gelatinous, naked, contractile, and furnished with setaceous tentacula, inhabiting fresh waters, and producing

its deciduous offspring, or eggs, from the sides. The hydra viridis inhabits the stagnant waters and slowly running streams of Europe, generally on the surface of plants, and appears like a little transparent green jelly, when contracted and transparent: when expanded it is a linear body, fixed at one end, and surrounded at the other by tentacula, or arms placed in a circle round the mouth, and gradually producing its young from the sides, which at first seem small papillæ, increasing in length, till they assume the form of the parent, and then dropping off. Like all its tribe, it has the power of reproducing parts which have been destroyed, and if cut or divided in any direction, each separate part becomes a perfect polype. See Adams on the Microscope. There are five species.

HYDRACHNA, a genus of insects of the order aptera: the generic character is, head, thorax, and abdomen united or connate; feelers two, jointed; eyes two, four, or six; legs eight, formed for swimming. The genus hydrachna, allied in the closest manner to that of acarus, under which the only species known to Linnæus were arranged, was first instituted by the ingenious Muller, by whose industrious researches many new and curious kinds have been discovered.

Among the larger insects of this genus is the hydrachna flaccida, so called, in order the more clearly to distinguish it from one or two others with which it may sometimes be confounded. Its size is that of a small pea, and its colour a very bright red: its shape is nearly globular, but the skin is of such a nature as to yield to every inclination of the body, so that the whole, when taken out of the water, has an irregularly flaccid appearance. This is most remarkable in the full-grown animal, which is also of a much more torpid nature than the rest of the genus, which are animals of great celerity of motion; and indeed the young or unadvanced individuals of the present species are of a more compact appearance, and swim with a greater degree of swiftness than the larger ones. The hydrachna flaccida is not very uncommon in stagnant waters.

Of all the hydrachnæ yet discovered by far the most elegant is the hydrachna geographica, so named from the fancied map-like distribution of its variegations. It is one of the largest of the genus, equalling the size of the former: it is occasionally seen in clear ponds and other stagnant waters, but is one of the rarer kinds: its shape is globular, and its colour a polished black, decorated with carmine-coloured spots and patches, which, in a certain light, are accompanied by a kind of gilded lustre.

Hydrachna roeseliana is named after Roessel, by whom it is figured in his well-known work on insects. It is of equal, or even superior size to that immediately preceding, which in many points it seems greatly to resemble; the ground-colour however in this is red, with black variegations, disposed in a different manner from those of the former. It is found, though not very frequently, in stagnant waters.

Among the smaller, or middle-sized hydrachnæ, one of the most common is the hydrachna extendens, which is of the size of a very small hemp-seed, and of a bright red colour, without any variegations; it is ex-

tremely nimble in its motions, and always carries the hinder pair of legs, which exceed the rest in length, in an extended posture.

Hydrachna araneoides is a small species, of a brown colour, clouded with red, and marked on the back by a very large oval patch of the same colour. It is found, like the rest, in stagnant waters, and has the habits of a young spider.

Some of the genus are distinguished by a kind of cylindric process at the end of the abdomen; of this kind is the hydrachna buccinator. It is a very small species, of a dark-brown colour, with a large rufous patch at the upper part of the body, the cylindric process being of a dull yellow. It is a native of stagnant waters.

The eggs of the hydrachnæ, which are small and round, are deposited in flat clusters, sometimes on the bodies of the napæ, and other water insects. The young, when first excluded, are furnished with six legs only, but after the first and second change of their skins, become eight legged insects.

HYDRARGYRUM, a name given in the pharmacopeia to mercury or quicksilver.

HYDRANGEA, a genus of the digunia order, in the decandria class of plants, and in the natural method ranking under the 13th order, succulentæ. The capsule is bilocular, birostrated, and cut round, or parting horizontally. There are three species, of which the hortensis is a very handsome and now a popular greenhouse plant.

HYDRASTIS, a genus of the polygamia order, in the polyandria class of plants, and in the natural method ranking with those of which the order is doubtful. There is neither calyx nor nectarium; there are three petals, and the berry is composed of monospermous acini. There is one species an herb of Canada.

HYDRAULICS. The science which has for its object the motion of fluids is called hydraulics; and its immediate application is to furnish us with the means of conducting water from one situation to another, by canals or aqueducts, and to elevate it by pumps, jets-d'eaux, and other hydraulic engines, either for the purposes of ornament or use.

In treating of this subject we shall commence with the simplest principles, and shall first speak of the discharge of fluids through small apertures.

When water flows from a vessel which has a hole or aperture in the bottom, small in comparison to the width of the vessel, the water descends vertically, and the surface appears smooth, but at three or four inches from the bottom the particles turn from this direction, and proceed on all sides with a motion more or less oblique towards the aperture. The same effect takes place when water flows through an aperture laterally. The tendency of the particles towards the aperture is a necessary consequence of their perfect mobility; for they will certainly be directed towards the point where there is the least resistance, and that point is the aperture.

It is also to be observed, that in this case; at a small distance from the bottom, a kind of funnel is formed in the water, the point of which corresponds to the center of the aperture; when, however, the water flows through a lateral orifice or aperture, there is formed

only a kind of half funnel, which does not appear to commence till the surface is near touching the upper side of the hole. It is probable that the funnel begins to form itself from the first moment of the flow; but it does not become perceptible till the surface is only at a small distance from the bottom.

It appears also, that the funnel commences higher or lower, according to the width of the bottom; and that the formation of it is less prompt or less perceptible, according to the proportion of the aperture to the extent of the bottom. The funnel is also augmented by any roughness which may exist at the sides or bottom of the vessel.

Water flows out of a small hole in the bottom of a vessel with a velocity equal to that which a ponderous body acquires in falling from a height equal to the vertical height of the surface of the fluid above the aperture.

The same law takes place in a lateral orifice; for the pressure of the fluid is equal (at the same depth) in all directions, and consequently produces the same degree of velocity. See **HYDROSTATICS**.

A fluid, in running out of an aperture, acquires a velocity sufficient to make it remount to a vertical height equal to that of the fluid above the aperture, in the same manner as a falling body acquires a velocity capable of making it ascend to the height from which it descended.

It is evident, from the theory of falling bodies, that if the velocity of the fluid in running through the aperture was uniformly continued, the fluid would move through a space double the height of the fluid above the aperture, in the same time that a falling body would employ in descending from that height.

The height being the same, the velocity of the fluid in running out of the orifice will always be the same, whatever the species of the fluid may be, and whatever its density. It is true, that when the fluid has more density it presses more forcibly, but then the mass is more considerable; and it is evident, that when the moving powers are proportioned to the masses which they put in motion, the velocities are equal.

The quantities of a fluid discharged in the same space of time through different orifices, supposing the vessels equally full during the whole of the experiment, are to each other as the products of the areas of the apertures by the square roots of the heights. For instance, it has been proved by experiment, that a circular orifice of an inch diameter, made in a thin vessel or partition, and under a surface of fluid four feet in height, will furnish, in one minute of time, 5436 cubic inches French.

If, therefore, it was an object to ascertain how much a circular orifice of two inches diameter, under nine feet of height from the surface of the water, would furnish in the same, the following proportion must be employed (it must be observed, that the orifice of two inches is four times as great as an orifice of one inch, because the areas of circles are as the squares of their diameters):

$$1 \times \sqrt{4} : 4 \times \sqrt{9} :: 5436 : x$$

Or at length

$$2 : 12 :: 5436 : 32616$$

12

$$2)653232$$

Somersetshire Plough

Norfolk Plough

Double furrow Plough

Fernald's sowing Machine

Therefore 32616 cubic inches of water will flow from an aperture of two inches in diameter in one minute, the orifice being made nine inches from the surface, which is supposed to be kept at that height the whole time.

If a vessel of a prismatic form is filled with water, and permitted to empty itself entirely through an orifice at the bottom, and the time that it consumes in emptying itself is observed; and if afterwards, having replenished the vessel, the water is made to flow through the same aperture, the vessel being kept full the whole time, there will run out in this second instance, during the same time that the vessel took to empty itself at first, a quantity of water, double that which runs out in the first case, in which the abstraction of the water diminishes the height, and consequently the velocity.

We often perceive water flow through lateral apertures, which, though small in comparison to the width of the reservoirs, cannot be regarded as having all their points at an equal distance from the surface of the fluid; such, for example, as the apertures through which water sometimes flows in mills. The common method of determining the quantity discharged is as follows: suppose, in the first place, the aperture to be stopped up by a plate of metal, which is perforated with a number of holes; if each of these holes is regarded as particular and insulated, the rapidity of the flow through each will be according to the correspondent height of the fluid; then if the number of holes are multiplied ad infinitum, or, which will amount to the same thing, if the plate is supposed to be entirely taken away, the velocity at each point of the supposed orifice will be according to the correspondent height of the fluid; and in estimating the quantity of water discharged, some attention must be paid to the inequality of the motion; yet it must not be asserted that this reasoning is entirely conclusive. In proportion as the sum of the small holes made in the plate is small in comparison with the size of the reservoir, the portions of water which flow through each hole are forced out by the absolute weight of the column above; but the moment that the number of apertures augment ad infinitum, and the streams of water which run through them become contiguous, it cannot be clearly said that the liquid flows in the same manner as through small insulated holes; yet as this hypothesis gives a result sufficiently conformable to experiments, it may be useful to preserve it, and the more so, as it leads to very simple calculations, and in all common questions this simplicity may be preferable to the minuteness of fractional operations.

The quantity of water which issues from these apertures in a given time is not so great as their size might at first suggest, because the stream is contracted by running out of each orifice, and that contraction extends to a distance nearly equal to half the diameter of the aperture; and the diameter of the contracted stream is to the diameter of the aperture a little more than as three to four, or as three and one-sixth to four, or nineteen to twenty-four; so that its area is to that of the aperture as ten to sixteen. It is nearly the same when water flows through lateral apertures. The contraction of the stream is a proof of what has been before stated, viz. that

withinside a vessel the lateral particles direct themselves towards the orifice with a motion more or less oblique; and this oblique motion may be decomposed into two forces, the one parallel to the plane of the orifice, and which contracts the stream; the other perpendicular to the same plane, and the only one which produces the efflux.

This contraction occurs also when water is made to flow through pipes, and that at the entrance of the water into the pipe, and not at its exit, where the stream preserves a cylindrical form. We shall prove that this contraction diminishes, in a sensible manner, the quantity of water which would naturally flow.

In order to ascertain these facts by experiments, many have been made. In all the following instances, the orifices through which the water flowed were pierced perpendicularly through plates of copper of about one-twenty-fourth of an inch thick, and the time of each experiment is reduced to one minute.

The constant height of the water above the centre of each orifice was 11 feet 8 inches 10 lines.

| | No. of cubic inches
furnished in 1 min. |
|--|--|
| Expt. 1. Through an horizontal circular orifice of $\frac{1}{2}$ inch (6 lines) diameter - | 2,311 |
| 2. Through ditto of 1 inch diameter - | 9,281 |
| 3. Through ditto of 2 inches diameter - | 37,203 |
| 4. Through an horizontal rectangular orifice of 1 inch long and $\frac{3}{4}$ inch wide - | 2,933 |
| 5. Through an horizontal square orifice of 1 inch the side - | 11,817 |
| 6. Through ditto of 2 inches each side of the orifice - | 47,361 |
| Constant height = 9 feet. | |
| 7. Through a lateral circular orifice of $\frac{1}{2}$ inch diameter - | 2,018 |
| 8. Through ditto of 1 inch diameter - | 8,135 |
| Constant height = 4 feet. | |
| 9. Through a lateral circular orifice of $\frac{1}{2}$ inch diameter - | 1,353 |
| 10. Through ditto, of 1 inch diameter - | 5,436 |
| Constant height = $\frac{7}{12}$ inch. | |
| 11. Through a lateral circular orifice of 1 inch diameter - | 628 |

It follows from the preceding table,

1. That the quantities of water discharged in the same time, by different apertures, under the same height of surface in the reservoir, are to each other nearly as the areas of the apertures. Compare together the results of the second and third experiments of which the areas of the orifices are in the proportion of one to four, and it will be found that the quantities of water afforded, viz. 9281 cubic inches, 37203, inches, are very nearly in the same proportion.

2. That the quantities of water discharged in the same time through the same aperture, under different heights of surface in the reservoirs, are to each other nearly as the square roots of the corresponding heights of the water in the reservoir above the centre of the aperture. Compare together the results of the 8th and 10th experiments, where the heights of

the reservoirs are nine and four feet, the square roots of which are three and two, and it will be found that the two quantities of water, 8135 cubic inches, 5436 cubic inches, which run through the same orifice of one inch diameter under the different heights of nine feet and four feet, are to each other nearly in the proportion of three to two.

3. That in general the quantities of water discharged in the same time through different apertures, under different heights of surface in the reservoirs, are to each other as the areas of the apertures are to the square roots of the heights of water in the reservoirs.

4. That in consequence of the friction, the small apertures furnish a less quantity of water in proportion than the great ones, under the same height of water in the reservoir; because, comparatively to the extent of the area of each orifice, there are more points of friction against the sides of the orifice in the small than there are in the great ones; for the circumferences do not diminish so much as the areas.

5. That of many apertures of equal areas, that of which the circumference is the least, will, on account of the friction, furnish more water than the others, under the same height of the reservoir; circular apertures are, for this reason, the most advantageous of all; for the circumference of a circle is the shortest line that can be made use of to inclose a given space, therefore there is less surface of friction relatively to the size of the area.

It is easy to perceive, that the quantity of water discharged in the table of experiments is not near so great as might be expected from the extent of the areas and the heights of the reservoirs. The quantity is in fact diminished by the friction, and still more by the contraction of the stream; for the velocity which is in proportion to the entire altitude of the fluid is not sensibly changed. Supposing, first, that the area of the stream is the same as that of the orifice; and supposing, secondly, that the stream is contracted, then the difference of the quantities afforded is as sixteen to ten; that is, supposing the area of the aperture to be diminished in the proportion of sixteen to ten, the discharge of the fluid out of vessels kept equally full may be determined with sufficient exactness. By the expression, an inch of water, is understood the quantity which flows out of a circular and lateral orifice of one inch diameter, the surface of the water being constantly kept seven-twelfths of an inch above the centre of the orifice. This is the case with the eleventh experiment in the preceding table, where it appears that the quantity of water furnished is 628 cubic-inches. Mr. Mariotte, who made the same experiment, found the quantity to be a little more; but it is probable that he might commit a small error, because the experiment just cited was made, M. Brisson informs us, with the utmost care and attention. A (French) pint of water, he adds, instead of weighing two pounds, as is commonly believed, is proved to fall short of that weight considerably, as will be evident by strictly examining that experiment.

When additional pipes are employed, it appears,

First, That the quantity of water discharged by different additional pipes, under the same height of water in the reservoir, is pro-

portional to the areas of the apertures, or to the squares of their diameters.

Secondly, That the quantities of water discharged through additional pipes of the same diameter, under different altitudes of water in the reservoir, are proportional to the square root of the altitude.

Thirdly, That in general the quantities of water discharged in the same space of time through different additional pipes, under different heights of water in the reservoir, are to each other nearly as the product of the square of the diameters of the pipes by the square root of the altitude of the reservoirs.

The efflux of water, therefore, through additional pipes, follows the same laws as water when discharged through apertures made in thin substances.

If the vessel AB (Plate Hydrostatics, &c. fig. 1.) is full of water, and the horizontal pipe D in the middle of its side, and the semicircle NEC described upon D, as a centre, with the radius, or semidiameter DC, or DN, the perpendicular DE to the diameter CDN, is the longest that can be drawn from any part of the diameter to the circumference: and if the vessel be kept full, the jet will spout from the pipe D to the horizontal distance MN, which is double the length of the perpendicular DE. If two other pipes, as F and G, be fixed into the side of the vessel, at equal distances above and below the pipe D, the perpendiculars FH and GI, from these pipes to the semicircle will be equal; and the jets spouting from them, will each go to the horizontal distance NK, which is double the length of either of the perpendiculars FH or GI.

Fluids, by their pressure, may be conveyed over hills and valleys, in bended pipes, to any height not greater than the level of the springs whence they flow. This the ancients were ignorant of; and therefore they usually built aqueducts (vast rows of arches, one above another, between two hills, at an immense expence of money, time, and labour) in order to convey water over them, across the valley.

This is now done to equal advantage, and at much less expence, by a range of pipes laid down one hill and up the other. If water is poured into one of the legs of the bended pipe ACB (fig. 2.) it will rise exactly to the same level in the other. The reason is obvious: in the leg A there are, suppose, two ounces of water, endeavouring by the force of gravity to descend with the force of two; this will thrust forward, buoy up and support an equal quantity of a like fluid in B; and the bottom of the machine C, against which both sides equally bear, will of consequence sustain a double pressure, or that of four ounces; and in the present case, will pretty well represent the prop, or fixed point, of a balance-beam; as the equal fluid columns AC and BC, may be admitted to denote equal weights, suspended on the balance-arms, counterpoising each other: so that the rise of fluids to their first level, thus considered, is a case truly statical; and all their other motions proceed only from weight added.

We have seen, that water will rise through bended pipes to the same level as the reservoir from which it proceeds. Upon the same principle, jets, or fountains, are formed; for if near the bottom of the vessel AB (fig. 1.) you fasten a small pipe *m*, bending upwards, the water will spout out through the pipe,

and rise nearly as high as the surface of the water in the vessel. It will not rise quite so high, because it is somewhat impeded by the resistance of the air, and the friction against the opening of the pipe, or adjutage.

It is always found necessary to increase the bore of the adjutage, or spouting-pipe, with the height of the reservoir; for if it is too small, the rising stream will want sufficient weight and power to divide the air, which being densest near the earth, a small stream of water, endeavouring to mount to a great height, will be dashed against it with so much violence, as to fall away in a mist, and be wholly lost.

There is a certain and fit proportion to be observed between the adjutage by which the jet is delivered, and the pipe conducting it from the head. In general, about five times the diameter of the adjutage, for jets under half an inch, and six or seven times for all above, will give the size of pipes of conduct pretty well; though it will always be an error on the right side, to have them rather larger than in strictness they ought to be, that the jet may always be freely supplied with water, and in due time.

For a like reason, if there is occasion for a cock to be placed in any part of the pipe of conduct, particular care must be taken that it should be there bigger in proportion, that the water may not be pinched, but that the cavity be left at least equal to the bore of the rest of the pipe.

The bore of an adjutage cannot be too smooth, or true. Those that are cylindrical are best; those that are bored conical, worst; because of the reflections of the water from the inclined sides of the machine, which, in the hurry of the issuing stream, will in them unavoidably be made.

Archimedes' screw (fig. 7.) deserves consideration, not only for its antiquity, but its usefulness in raising water. It consists of a long cylinder, with a hollow pipe-tube, or groove, coiled about it, as represented in the figure. It is placed in a position oblique to the horizon, with the lower end in the water, the other being supported on the lower part of the winch I, by which the screw and cylinder are turned round. As soon as the screw is immersed in water, it immediately rises in the machine by the orifice C, to the level of the surface of the water E; and if the point of the helix, or spiral, which in the beginning of the motion is coincident with the surface of the water, happens not to be on the lower side of the cylinder, the water will, upon the motion of the screw, move on in the helix, until it comes to the point which is on the under side, and coincident with the watery surface: when it is arrived at that point, it cannot afterwards possess any other part of the spiral, than that which is upon the lowest part of the cylinder, for it cannot move towards H, because H is situated higher; and since this will ever be the case, after the surface of the water in the helix has attained the point E, it is plain that it must always be on the under side of the cylinder. But since the cylinder is in motion, every part of the spiral screw from EF, will by degrees succeed to the under part of the cylinder; the water therefore in the helix must succeed to every part from E to F, as it comes to the lower side; that is, it must ascend on the lower part of the

cylinder through all the length of the pipe, until it comes to the orifice at top, where it will run out.

Of all the machines the ancients invented to raise water, it appears that though Archimedes' screw was the most curious, the tympanum, mentioned by Vitruvius, elevated the greatest quantity at once; a brief description of this may suffice, as preparatory to the account of machines made in imitation of it, but more ingenious and more perfect.

The tympanum is a great hollow wheel, forming a kind of barrel or drum (as its name imports) composed of several planks joined together, well calked and pitched, and having a horizontal axle on which it turns: the interior of this drum is divided into eight equal spaces by as many partitions placed in the directions of the radii; each space or cell has an orifice of about half a foot in the rim of the drum or wheel, so shaped as to facilitate the admission of the water; moreover, there are eight hollow channels running contiguous to each other, and parallel to the axle of the wheel, each corresponding to one of the eight large cells; into these channels the water passes out of the cells just mentioned, and after running along the channels to a convenient distance, it escapes through orifices into a reservoir placed just under the axle. Thus the water is elevated through a vertical space equal to the radius of the hollow wheel. When the tympanum is used to raise water from a running stream, it is moved by means of float boards which are impelled by the stream; but when it is employed to raise stagnant water, there is commonly a smaller wheel on the same shaft, which is turned by men walking in it, as in the old walking crane. The chief defect of this machine is that it raises the water in the most disadvantageous situation possible; for the load being found always towards the extremity of a radius of the wheel, the arm of the effective lever which answers to its increases through the whole quadrant the water describes in passing from the bottom of the wheel to the altitude of its centre; so that the power must act as if it was applied at a winch handle, and cannot therefore act uniformly.

Mr. H. Sarjeant, of Whitehaven, contrived a very cheap engine for raising water, for which the Society for the Encouragement of Arts awarded him a silver medal in the year 1801. A sketch of this simple invention is given in fig. 8.

This engine was erected at Irton-hall, which is situated on an ascent of 60 or 61 feet perpendicular height: at the foot of this elevation, about 140 yards distant from the offices, there runs a small stream of water, and in order to procure a constant supply of that necessary fluid, the object was to raise such stream to the house for culinary and domestic uses. With this view, a dam was formed at a short distance above the current, so as to cause a fall of about four feet: the water was then conducted through a wooden trough, into which a piece of leaden pipe, two inches in diameter, was inserted, and part of which is delineated at A.

The stream of this pipe is directed in such a manner as to run into the bucket B, when the latter is elevated; but as soon as it begins to descend, the stream passes over it, and flows progressively to supply the wooden trough or well, at the foot of which stands the

forcing-pump C, being three inches in diameter.

D is an iron cylinder attached to the pump-rod, which passes through it: such cylinder is filled with lead, and weighs about 240 lbs. This power works the pump, and forces the water to ascend to the house through a pipe one inch in diameter, and which is 420 feet in length.

At E is fixed a cord, which, when the bucket approaches to within four or five inches of its lowest projection, extends, and opens a valve in the bottom of the vessel through which the water is discharged.

An engine in a great degree similar to this was erected some years ago by the late James Spedding, esq. for a lead mine near Keswick, with the addition of a smaller bucket which emptied itself into the larger near the beginning of its descent, without which addition it was found that the beam only acquired a libratory motion, without making a full and effective stroke.

To answer this purpose in a more simple way, Mr. Sarjeant constructed the small engine in such manner as to finish its stroke (speaking of the bucket end) when the beam comes into an horizontal position, or a little below it. By this means the lever is virtually lengthened in its descent in the proportion of the radius to the cosine, of about 30 degrees, or as seven to six nearly, and consequently its power is increased in an equal proportion.

It is evident, that the opening of the valve might have been effected, perhaps better, by a projecting pin at the bottom, but Mr. S. chose to give an exact description of the engine as it stands. It has now been some years in use, and completely answers the purpose intended.

The only artificers employed, except the plumber, were a country blacksmith and carpenter; and the whole cost, exclusive of the pump and pipes, did not amount to 5*l*. Pumps are engines depending also on the principles of hydraulics. See PUMP.

HYDRO-CARBONATES, combinations of carbon with hydrogen. A gas of this name is obtained from moistened charcoal by distillation.

HYDROCELE. See SURGERY.

HYDROCHARIS, the *little water-lily*, a genus of the enneandria order, in the diœcia class of plants, and in the natural method ranking under the first order, palmæ. The spathe of the male is diphyllous; the calyx trifid; the corolla tripetalous; the three interior filaments styliiferous. The female calyx trifid; the corolla tripetalous; the styles six; the capsule has six cells, and is polyspermous inferior. There is only one species, a native of Britain, growing in slow streams and wet ditches. It has kidney-shaped leaves, thick, smooth, and of a brownish-green colour, with white blossoms. There is a variety with double flowers, of a very sweet smell.

HYDROCOTYLE, *water-navel wort*, a genus of the digynia order, in the pentandria class of plants, and in the natural method ranking under the 45th order, umbellatæ. The umbel is simple; the involucre tetraphyllous; the petals entire; the seeds are half round and compressed. There are 15 species, none of which are ever cultivated in gardens. One of them, a native of Britain, growing in marshy grounds, is supposed by

the farmers to occasion the rot in sheep. The leaves have central leaf-stalks, with about five flowers in a bundle; the petals are of a reddish white.

HYDROGEN, in chemistry, one of the simple combustibles, the base of hydrogen gas, formerly called inflammable air.

HYDROGEN-GAS. To obtain this, put one part of iron-filings into a retort, attached to the pneumatic cistern, and pour thereon two parts of sulphuric acid previously diluted with four times its bulk of water. Immediately the mixture begins to boil or effervesce with violence, and air-bubbles rush abundantly from the beak of the retort. Allow them to escape for a little, till you suppose that the common air which previously filled the retort has been displaced by the newly generated air. Then place an inverted jar over the beak of the retort. The bubbles rush in abundantly and soon fill the jar.

It was obtained by Dr. Mayow and by Dr. Hales from various substances, and had been known long before in mines under the name of the fire-damp. But Mr. Cavendish ought to be considered as its real discoverer; since it was he who first examined it, and pointed out the difference between it and atmospheric air, and who ascertained the greatest number of its properties.

Hydrogen gas, like air, is invisible and elastic, and capable of indefinite compression and dilatation. Its specific gravity differs according to its purity. Kirwan found it 0.00010; Lavoisier 0.000094, or about 12 times lighter than common air. All burning substances are immediately extinguished by being plunged into this gas. It is incapable therefore of supporting combustion. Small animals, when they are obliged to breathe it, die; but large animals resist its action longer. Scheele found that he could breathe it for some time without much inconvenience; but Fontana, who repeated the experiment, affirmed that this was owing to the quantity of common air contained in the lungs when he began to breathe; for on expiring as strongly as possible before drawing in the hydrogen gas, he could only make three respirations, and even these three produced extreme feebleness and oppression about the breast.

The ingenious Mr. Davy, professor of chemistry in the Royal institution, to whom we are indebted for many curious and important, but rather hazardous experiments on respiration, made chiefly upon himself, after a complete exhaustion of his lungs, found great difficulty in breathing this gas for so long as half a minute. It produced uneasy feelings in the chest, momentary loss of muscular power, and sometimes a transient giddiness.

Pilatre de Rozier publicly verified the assertions of Scheele. He breathed hydrogen gas six or seven times from a bladder without inconvenience. To demonstrate that it was really hydrogen gas which he was breathing, he made a strong inspiration, and expired the air slowly through a long tube. On bringing a lighted taper to the end of the tube, the gas took fire, and continued to burn for some time. It was objected to him, that the gas which he breathed was diluted with common air. To shew that this was not the case, he mixed together one part of common air and nine parts of hydrogen gas, and having drawn

the mixture into his lungs, he threw it out the same way. On applying a taper to the tube, the whole of the gas exploded in his mouth, and almost stunned him. At first he thought that the whole of his teeth had been driven out, but fortunately he received no injury whatever.

If a phial is filled with hydrogen gas, and a lighted candle brought to its mouth, the gas will take fire, and burn gradually till it is all consumed. If the hydrogen gas is pure, the flame is of a white colour; but if the gas holds any substance in solution, which is often the case, the flame is tinged of different colours, according to the substance. It is most usually reddish, because the gas holds in solution a little charcoal. A red-hot iron likewise sets fire to hydrogen gas. From my experiments it follows, that the temperature at which the gas takes fire is about 1000°.

If pure oxygen and hydrogen gas be mixed together, they remain unaltered; but if a lighted taper be brought into contact with them, or an electric spark be made to pass through them, they burn with astonishing rapidity, and produce a violent explosion. If these two gases be mixed in the proportion of one part in bulk of oxygen gas and 2.527 parts of hydrogen gas, or, more accurately, 85 parts by weight of oxygen gas and 15 of hydrogen gas, they explode over water without leaving any visible residuum; the vessel in which they were contained (provided the gases were pure) being completely filled with water. But if the explosion be made in a close vessel, there is always found instead of them a quantity of water exactly equal to them in weight. This water must be composed of these two gases; for it did not previously exist in the vessel, and no other substance besides the gases were introduced. Water then is composed of oxygen and hydrogen; and the combustion of hydrogen is nothing else but the act of its combination with oxygen.

When two parts (in bulk) of hydrogen gas are mixed with six parts of common air, the mixture explodes with equal violence; and after the explosion, the bulk of the mixture is reduced to five parts. The whole of the hydrogen gas is consumed, and likewise all that part of the common air which consists of oxygen gas, and there is formed a quantity of water equal in weight to these two bodies. This experiment is often employed to ascertain the purity of hydrogen gas. Common air and the hydrogen gas to be examined are mixed in certain proportions in a glass tube, graduated and closed at one end; they are then fired by an electric spark. The purity of the gas is proportional to the diminution of bulk. Thus, when the bulk of a mixture of two parts of hydrogen gas and six parts of air is diminished after the explosion to five parts, the hydrogen gas may be considered as pure; if only to six, it contains some foreign ingredients, and so on. This method of detecting the purity of hydrogen gas was first employed by Berthollet. Volta, indeed, had employed it before him; but for a different purpose.

Hydrogen gas is not sensibly absorbed by water, though left for some time in contact with it. But by artificial pressure water may be made to absorb about the third part of its bulk of that gas. The taste of the water is not sensibly altered. Mr. Paul, who first formed this compound, informs us, that it is

useful in inflammatory fevers and in nervous complaints, but it is injurious in dropsy.

Hydrogen gas dissolves sulphur, phosphorus, and carbon. The compounds are called sulphureted, phosphureted, and carbureted hydrogen gas. See AIR, CHEMISTRY, &c.

HYDROGENIZED sulphurets, certain bases combined with sulphureted hydrogen.

HYDROGRAPHY, the art of measuring and describing the sea, rivers, lakes, and canals.

With regard to the sea, it gives an account of the tides, counter-tides, soundings, bays, gulphs, creeks, &c. as also of the rocks, shelves, sands, shallows, promontories, harbours, the distance and bearing of one port from another, with every thing that is remarkable, whether out at sea or on the coast.

HYDROLEA, a genus of the digynia order, in the pentandria class of plants, and in the natural method ranking with those of which the order is doubtful. The calyx is pentaphyllous; the corolla rotaceous; the filaments at the base are cordate; the capsule is bilocular and bivalved. There are four species, herbs of the East and West Indies.

HYDROMETER, an instrument much used for determining the specific gravities of liquids. It usually consists of a hollow sphere of glass or metal B, and balanced by another *b* below, containing quicksilver, or a metallic weight. Fig. 19. The larger ball has a shorter neck at C, into which is screwed the graduated stem AC, which by a small weight at A causes the instrument to descend in the fluid with part of the stem. When this instrument is swimming in the jar ILMK, the part of the fluid displaced by it will be equal in bulk to the part of the instrument under water, and equal in weight to the whole instrument. This instrument, therefore, marks the differences in the density of fluids by the place at which the surface cuts the stem as it floats, or by the proportionate addition or diminution of weight which is required to make it float at the same level in each.

Beaumé's areometer is often referred to in the works of French chemists. The inventor seems to have been led to a method of making instruments of this kind, which should agree with each other by reflecting on the way in which thermometers are graduated, that is, by means of an interval between two stationary points of temperature. Thus M. Beaumé adopted two determinate densities, in order to mark an interval in the stem of his hydrometer. These were that of pure water, and that of water containing $\frac{1}{2}$ parts of its weight of pure common salt at 10° Reaumur or 57° Fahrenheit. The instrument (represented by fig. 20.) was so balanced as to sink in the water to 0 near the top of the stem. In the saline solution the latter emerged more, and a certain additional portion appeared above, which was assumed to contain 15 degrees. By means of a scale and compasses, a scale of equal degrees was thus formed, adapted to the length of the stem, and being fixed within it, at a proper height, the latter was sealed at the blow-pipe without altering the weight. It is usually constructed in two pieces, to avoid an inconvenient length; one of which serves for the lower, the other for the higher, degrees of density. The glasses may be procured from the makers of thermometers, and it is convenient to have a

passage from the top quite down to the lower bulb for introducing the quicksilver, which being adjusted, may be secured there by a small morsel of cork. It is obvious that persons of ingenuity may adapt such instruments to their own purposes, by fixing on two liquids of known specific gravities to serve as the extremes of their scale, and may thus apply them to the trial of all liquids, from ether to sulphuric acid, in respect to gross differences, or for the purpose of having them of uniform strength. But the instrument is not to be depended on for those accurate reports on the specific gravity of liquids which are expected in detailing chemical experiments.

Fahrenheit contrived a more accurate metallic hydrometer, having a very slender stem, terminating in a small dish. The middle, or half-length of the stem, is distinguished by a fine line across. In this instrument every division of the stem is rejected, and it is always immersed to the line by means of weights put into the dish. Thus, as the part immersed is constantly of the same magnitude, and the whole weight of the hydrometer is known; this last weight, added to the weight in the dish, will be equal to that of the fluid, displaced by the instrument. Consequently, as the whole weight of the hydrometer and its load, when adjusted in distilled water, is to 1.000, so is the whole weight when adjusted in any other fluid, to the number expressing the specific gravity of that fluid.

Were the instrument constructed so that it should displace exactly 1.000 grains of distilled water at a mean temperature, the grains to be added or taken away for any other fluid would express the difference of the specific gravity at once. But as this would require much nicety, the weight of the instrument and its load adjusted in distilled water may be ascertained, and a set of decimal weights provided, each of which should bear the same proportion to its nominal value in grains that the whole adjusted in distilled water did to 1.000. By this, or by the former expedient, the trouble of calculation may be avoided; but those who use the instrument often will find it expedient to construct a set of tables adopted to the same purpose. See SPIRITS.

HYDRO-OXIDES, metallic oxides combined with water.

HYDROPHOBIA. See MEDICINE.

HYDROPHILUS, a genus of insects of the coleoptera order. The generic character is, antennæ clavate-perfoliate; hind legs villose, formed for swimming. The principal European species of this genus, which is not an uncommon insect in our own country, is the *hydrophilus piceus*, perhaps the largest of the British coleoptera, if we except the *lucanus cervus*; measuring nearly an inch and half in length. It is entirely black, and of a smooth surface, and is particularly distinguished by the form of its thorax, which is produced beneath into a very long and sharp-pointed spine, stretching to a considerable distance down the abdomen; the hind legs are furnished on each side with strong, but very fine, hairs. It is a native of stagnant waters, where its larva is principally observed to prey on the smaller kind of water snails, and is distinguished by a particularity in the highest degree remarkable; this consists in the apparently anomalous situation of the legs, which seem, unless very accurately considered, to be placed, not beneath the thorax, as

in other insects, but on the upper part, and thence to be deflected towards the sides. This uncommon appearance, however, is not owing to a real dorsal insertion of the legs, but principally to the peculiar shape and position of the head; and the deception is so much heightened by the inverted posture in which the insect generally swims and rests, that it is by no means easy, even for the most scientific observer, to divest himself of the erroneous idea beforementioned.

The larvæ of the hydrophils are supposed to remain about two years before they change into pupæ or chrysalides. When the larva is arrived at its full growth, it secretes itself in the bank of the water it inhabits, and having formed a convenient cavity or cell, lies dormant for some time, after which it divests itself of its skin, and appears in the form of a chrysalis, in which state having continued for some time longer, it again delivers itself from its exuviae, and appears in its complete or beetle form. When first disengaged from the skin of the chrysalis, it is of a pale colour, and very tender; but in the space of a few hours the elytra, or wing-cases, acquire a degree of strength and colour, which gradually grows more and more intense, till the animal, finding itself sufficiently strong, comes forth from its retreat, and commits itself in its new form to the waters.

The male is distinguished from the female by the structure of the fore legs, which are furnished, near the setting on of the feet, with a sort of horny, concave flap or shield; the legs of the females being destitute of this part.

The female of the *hydrophilus piceus* affords an example of a faculty which seems to be exercised by no other coleopterous insect, viz. that of spinning a kind of web or flatish circular case of silk, which it leaves floating on the water, and in which it deposits its eggs. This case is terminated on its upper surface by a lengthened conical process resembling a horn, of a brown colour, and of a much stronger or denser nature than the case itself, which is white. The young larvæ, as soon as hatched, make their escape from the envelopement of the case, and commit themselves to the water.

The *hydrophilus caraboides* is a species measuring about three quarters of an inch in length, and is of a polished black colour, and of an oval shape.

The genus *hydrophilus* has been greatly increased by the persevering researches of modern entomologists. Mr. Marsham enumerates 28 British species.

HYDROPHYLLAX, a genus of the monogynia order, in the tetrandria class of plants. The calyx is tetrapartite; the corolla funnel-shaped; the fruit two-edged and one-seeded. There is one species, an aquatic of the East Indies.

HYDROPHYLLUM, *water-leaf*, a genus of the monogynia order, in the pentandria class of plants, and in the natural method ranking with those of which the order is doubtful. The corolla is campanulated, with five melliferous longitudinal stria on the inside; the stigma is bifid; the capsule globose and bivalved. There are two species, the *virginianum*, or *water-leaf* of Morinus, grows naturally in Canada and many other parts of America on moist spongy ground. The root

is composed of many strong fleshy fibres, from which arise many leaves with footstalks five or six inches long, jagged into three, five, or seven lobes, almost to the mid-rib, indented on their edges. The flowers are produced in loose clusters hanging downward, are bell-shaped, and of a dirty white colour.

HYDROSCOPE, an instrument antiently used for the measuring of time. The hydro-scope was a kind of water-clock, consisting of a cylindrical tube, conical at bottom: the cylinder was graduated, or marked out with divisions, to which the top of the water becoming successively contiguous, as it trickled out, the vertex of the cone pointed out the hour.

HYDROSTATICAL BALANCE, a kind of balance contrived for the easy and exact finding the specific gravities of bodies, both liquid and solid. See **HYDROSTATICS**.

HYDROSTATICS have for their object the weight and pressure of fluids; and in this branch of science the art of determining the specific gravities of bodies is usually included, but this we have already been under a necessity of anticipating. Archimedes, among the antients, accomplished the most remarkable discoveries in this science. He is honoured even at this day, as the inventor of the ingenious hydrostatic process, by which the purity or baseness of a crown of gold was ascertained. Among the moderns we are indebted to Galilæo, Torricelli, Descartes, Pascal, Guglielmini, and Mariotte, for the best information on this subject; and by their experiments (which are as curious as they are decisive) we are instructed in what we may expect or fear from the power of fluids violently acted upon by the principle of gravity, and in what manner and upon what principles we may employ, for the use of man, the hydraulic machines.

It has been observed in another place (See **GRAVITATION**), that the propensity which bodies have of approaching towards the earth, or perhaps towards its centre, is the only cause of what we term weight or gravity, and that it is by the continual efforts which they make to obey that law, that they press upon every obstacle which impedes their progress. As fluids, like solid bodies, are impelled by their gravity, so in this case they press upon every object which opposes their fall; but from their nature they press in a different manner from solid bodies; hence arise the peculiar phenomena concerning which we are now to inquire.

Fluids are substances, the component parts of which are moveable among themselves, having scarcely any cohesion one with another, and moving independently of each other. Some philosophers have included in this definition what they term the grosser fluids, as, for example, a heap of corn, a heap of shot, of sand, &c. as well as the rarer and more elastic fluids, as common air, and all other aeriform substances. The proper objects, however, of the hydrostatic science, are those fluids which, in common language, are termed liquids, or those which always present to us a plane surface, level or parallel to the horizon.

All liquid substances are not equally so; hence it follows, that the laws of hydrostatics apply with less exactness in proportion as those substances depart from perfect fluidity. Water and oil both flow when the vessels, which contain them, are either overturned or

broken; but the effusion of oil is slower than that of water, because the particles of oil have more cohesion among themselves. The most singular effects in hydrostatics principally depend, perhaps, upon the extreme minuteness of the particles of fluids, but at least upon their great mobility.

To preserve a lucid order in the consideration of this subject, it will be necessary to divide the objects of our inquiry into three branches. In the first place, therefore, we shall consider in what manner the principle of gravity acts on the particles of fluids, and the phenomena which it produces in the fluids themselves; as well as their action against the sides, the bottoms, and tops of the vessels in which they are contained. Secondly, in what manner fluids of different densities act upon each other; and thirdly, the action of fluids on bodies immersed in them.

I. In pursuing the first object of this inquiry, it may be established as an axiom:

1. That the parts of the same fluid act with respect to their weight or pressure, independently of each other.

This property arises from their having scarcely any cohesion among themselves. It is otherwise with solid bodies; their several parts adhering together, they press in one common mass; hence the falling of solid bodies is productive of a different effect from that of liquids. We dread the falling of a pound of ice upon our heads, while we are much more indifferent concerning that of a pound of water. The latter, in its descent, is divided by the resistance of the air, by which some of its parts are retarded more than others; and the swiftness of the whole mass is still more retarded by this division than it otherwise would be; for by being thus divided it requires a larger surface, which abates its effect. On the contrary, a solid body falls upon a small space, which receives its whole force. Hence it follows, that angular bodies falling upon any part of the human frame are more dangerous than flat or plane ones of the same weight, and descending from the same height.

It follows from this principle, that if an aperture is made at the bottom of a vessel full of any fluid, in order to prevent the flowing out of the liquor, it is only necessary to counteract the weight of that column of fluid which has the aperture for its base, and that to counteract that weight it is the same whether the vessel is full of liquor, or whether it contains only a column, the base of which shall be equal to the aperture at the bottom.

Let the cylindrical vessel of glass A B (Plate Hydrostatics, fig. 9.) have a hole in the bottom at C, furnished with a cylindrical ferule of copper of an inch diameter D, which is to be stopped with a piston G, or the sucker of a pump well fitted to the ferule, and oiled, that it may yield to a moderate pressure. Let the piston be supported by a small rod G H, fastened at H to the silk which unites with the portion of the pulley M, with which the extremity of the lever M N is furnished, and which has for its center of motion the point L. The other portion of the pulley N, which terminates the other extremity of the lever, is also furnished with lines of silk, which support the small bason or scale I. Upon the copper ferule D then fit a cylindrical tube of glass F E, the interior diameter of which is equal to that of

the ferule, and its height equal to that of the vessel A B. When the apparatus is disposed in this manner, fill the tube E F with water, and continue to put small weights into the scale I, until the piston begins to rise. Afterwards take away the glass tube E F, and place the piston G in the copper ferule D, and pour water into the large vessel A B, and it will appear that the same weights as before in the bason I, will raise up the piston when the larger vessel A B is entirely full. Hence it follows that there is the same power to be counteracted, whether there rests upon the piston only a column of water of its own size, or whether the vessel A B is entirely full. Such a column, therefore, presses upon its base independently of the rest of the water contained in the vessel.

To account for this, let us suppose all the water in a vessel to be divided into several columns, 1, 2, 3, 4, 5, (fig. 10.) each composed of an equal number of parts. If the bottom of the vessel, which serves for the base and support of all the columns, is opened in *a*, the column 3, being no longer supported, will descend through the aperture, sliding between the two columns 2 and 4, which are supported by the parts of the bottom of the vessel *b* and *c*, all the moveable parts of which become (if we may use the expression) small rollers, which retard the fall only in a very slight degree. This effect is the result of the small degree of cohesion between the parts of the fluid. If the columns 1 and 2 on the one part, and 4 and 5 on the other, were composed of parts adhering together, they would retard each other in their descent during their whole length, in the same manner as a wax candle would do; and by the fall of the column 3, a void would be made between them. But as all the particles are extremely minute, moving easily upon each other, they descend when the summit of the column 3 begins to descend, having no longer any support from that side; and the superficies of the whole mass descends in the same manner, though only one of the columns caused the flow from its fall. When the parts have a degree of viscosity, as those of oily fluids, or when the mass of the flowing liquor has much more of breadth than of height, the void which the descending column leaves above it is easily perceived, for then the surface, instead of being plane and even, is hollow in the middle, and assumes a funnel-like form, because the adjacent parts do not arrive with sufficient swiftness to replace those which descend through the aperture; besides the pressure of the air above, the aperture is stronger than its resistance below.

From what has been now stated, it is easy to perceive how fluids differ from solids in the phenomena of gravitation. If the vessel A B (fig. 9.) being full of water, and the tube E F being removed, it was required to raise up the piston G; all that is necessary in this case is, to support the weight of the column of water directly above the piston, because this column can move independently of the remainder; but if the whole mass of water was converted into ice, then the mass ceasing to be a liquid, and all its parts adhering together, to raise up the piston it would be necessary to support the weight of the whole mass.

2. Fluids press equally in all directions.

In other words, they not only press from

the top to the bottom like other bodies, but they also press, according to their weight, upon all bodies that oppose them in a lateral direction, and even from the bottom to the top. Hence, if a cask is filled with liquid oil, the oil will run out if an aperture is made in the side, but when it is congealed it will not run out on account of its having become a solid body, for solid bodies press only from their vertex to their base, and not laterally.

To understand properly this lateral pressure of fluids, and also that which they exert from their base towards their vertex, it is necessary to consider them as a mass of small globules deposited in a vessel; and to remember that these minute globules are not arranged regularly as upon a cord, but that very frequently one column exercises its pressure between two others, and has a propensity to displace them, as may be seen in fig. 11. where the perpendicular pressure which is made opposite to the point *d*, is directed by the lateral columns towards the sides, *e f*, of the vessel, in such a manner, that if the vessel was open in those places the liquid would flow out, on account of the great mobility of its parts. It is by the same mode of reasoning, that the pressure of fluids, from their base towards their vertex, is accounted for.

It is upon this principle that the water, elevated by the New River water-works, after having descended from a basin in a vertical pipe, and then after having flowed horizontally in a succession of pipes under the pavement, is raised up again, through another pipe, as high as the fountain at the Temple Garden. It is also upon this principle that a vessel may be filled either at the mouth or at the bottom indifferently, provided that it is done through a pipe, the top of which is as high as the top of the vessel to be filled. Hence it follows, that when piers, aqueducts, reservoirs, or other hydraulic works for the retention of water are to be constructed, it becomes necessary to proportion their strength to the lateral pressure which they are likely to sustain, which becomes greater as the height of the water is more considerable. Nearly the same precautions are necessary to be taken with respect to what some philosophers call the grosser fluids, which also have a propensity to expand, as well on account of the smallness of their parts as from the small degree of cohesion which exists between them. Walls designed to support terraces ought to be sufficiently strong to resist the lateral pressure of the earth and rubbish which they are to sustain, since this pressure will be greater as the particles of earth, and of the other materials of which the terraces are composed, are less bound together, and in proportion as the terraces are more elevated.

3. All the parts of the same fluid are in equilibrium with each other, whether they are contained in one vessel or many, provided they communicate with each other; and their surfaces also are always in a plane parallel to the horizon.

This is a consequence of the principle which has been before established: for, since the particle *k* (fig. 11.) would be raised from the base towards the top, unless a column equal to the column *ik*, pressed upon it to retain it in its place; it follows that to be in equilibrium, the upper extremities of the two columns should be in the same horizontal

plane, or in points equally distant from the centre of the earth; which points, however, cannot be found by a right line; for in the distance of a thousand fathoms there is about one foot difference in the perpendicular height. From this property of fluids it follows, that water conducted by pipes placed in the earth, will remount as high as the place whence it flowed, whatever the depth under ground through which it may have been conducted by the pipes. It is customary to allow half an inch of inclination in the length of six feet, to counteract the resistance produced by friction; but it is clear from what has been said, that this is not absolutely necessary, for however long the passage might be the water would still ascend as high as the place whence it came, but it would require a little longer time to accomplish the ascent. We are enabled, upon this principle, to account for the springs which are sometimes found on the tops of mountains. Such waters flow from mountains still more elevated (whether they are far or near), by subterraneous canals. It follows from this principle, that if there are many reservoirs which communicate together, it is necessary only to see one of them to know the height of the water in the others; for it must necessarily be of the same height there as in all the rest.

From what has been observed, viz. that when all the parts of the same fluid are in equilibrium, their surfaces will also be in a plane parallel to the horizon, or, in other words, every part of the surface at an equal distance from the centre of the earth, it follows, that when the surface of water is very large, it becomes necessarily and sensibly convex. This is easily perceived at sea, where the masts of ships are observed at a distance before any other part of the ship can be distinguished.

It follows from the equal pressure of fluids in all directions, that the horizontal bottom of a vessel sustains just the pressure of a column of the fluid, whose base is the area of the bottom of the vessel, and whose perpendicular height is equal to the depth of the fluid. Thus in the vessel *A B C* fig. 12. the bottom *B C* does not sustain a pressure equal to the whole quantity of fluid contained in the vessel, but only of a column whose base is *C B*, and height *C E*. Also in the vessel *F G H*, the bottom *G H*, fig. 13, sustains a pressure equal to what it would be if the vessel were as wide at the top as bottom.

This leads us to notice what is called the hydrostatical paradox, which is thus expressed, "that a quantity of fluid, however small, may be made to counterpoise a quantity however large." Thus if to the wide vessel *A B*, fig. 14, the tube *C D* is attached, communicating with *A B*, and then water be poured into either of them, it will stand at the same height in both, consequently there is an equilibrium between them.

It may be thus illustrated: Let *A B D G*, fig. 15, represent any cylindrical vessel, to the inside of which is fitted a cover *C*, which will slide up and down without suffering any water to pass between the edges. In the cover is inserted a small tube, *C F*, which is open at top, and communicates with the inside of the cylinder beneath the cover at *G*. The cylinder is filled with water, and the cover put on. Then if the cover is loaded with a weight, as a pound, it will be depressed, and the water

rise in the tube to *E*, and the weight will be sustained. If another weight be added, the water will rise to *F*, and the weight sustained, and so on, according to the weight added, and the length of the tube. Now the weight of the water in the tube is but a few grains, yet its lateral pressure serves to sustain as much as the weight of a column of water whose base is equal to that in the tube. Thus the column *E d* produces a pressure in the water contained in the cylinder, equal to what would have been produced by the column *A a d D*; and as this pressure is exerted equally every way, the cover will be pressed upwards with a force equal to the weight of *A a d D*; consequently if *A a d D* weigh a pound, *E C* will sustain a pound: and the like of any other heights and weights.

One of the most useful machines to shew that a small quantity of water is capable of great pressure, is the hydrostatic bellows. This machine (fig. 16.) consists of two thick circular or oval boards, united to each other by leather, like a pair of common bellows, or a barber's puff. Into the lower board a pipe *B*, several feet high is fixed. Now, in shewing experiments with this simple machine, which the reader might easily make, let water be poured into the pipe at its top, which will run into the bellows, and separate the boards a little: then, to shew how much a small quantity of water will be able to effect by pressure, let weights be laid upon the upper board. If we pour more water into the pipe, it will as before run into the bellows, and raise up the board with all the weights upon it. And though the water in the tube should weigh in all but a single pound, yet the pressure of this small force upon the water below in the bellows, will support the weights, which are perhaps a hundred pounds; nor will they have weight enough to make them descend, and conquer the weight of the water, by forcing it out of the mouth of the pipe.

Upon the principle of the upward pressure of fluids, a piece of lead may be made to swim in water, by immersing it to a proper depth, and keeping the water from getting above it. Let *C D*, fig. 17, be a glass tube open throughout, and *G* a flat piece of lead half an inch thick, fitted exactly to the lower end of the tube, but not to go within it. By means of the packthread *L*, the lead is held close to the bottom of the tube, and in this situation it is immersed in the water of the vessel *K* to somewhat more than eleven times its own thickness, because lead is more than eleven times heavier than water; then the thread *L* may be let go, but the lead will not fall, but be sustained by the upward pressure of the water below it. If some water be poured upon the lead, or if the tube be raised a little, the lead will fall by its own weight, which will then be too heavy for the pressure of the water round the tube, upon the column of water below it.

It is clear, from the foregoing principles, that a tun filled with water, may be burst by pressing it with some pounds additional weight of the fluid, through a tube, which may be supposed to be from twenty-five to thirty feet in height; for from what has been said, it necessarily follows, that the small quantity of water which the tube contains, presses upon the bottom of the tun as much as if a column of water had been added as wide as the tun itself, and as long as the

tube, which would evidently be an enormous weight.

II. The effects of gravity on fluids of different densities will, from what has preceded, not be very difficult to comprehend.

It has been observed, that fluids are masses of small bodies moveable with great facility among themselves independently of each other, pressing separately, and in proportion to their masses.

It is proved also by chemical analysis, that even these minute particles are composed of particles still smaller. Now whether it results from the interposition of caloric in greater or less quantities, which we know is the cause of all fluidity, and also of the difference that exists between the incompressible and elastic fluids; or whether it may depend upon the shape or size of the particles, which, as in solid bodies, may increase or diminish the porosity, it is certain, that there is a considerable difference with respect to density in different fluids.

From this difference in point of density, a separation may be observed generally to take place, soon after mixing two heterogeneous fluids together, unless this effect is counteracted by some more powerful cause. It has been observed, that the particles, according to their weight, press independently of each other. Those therefore which have the most density, having more power to gain possession of the lower part of the vessel which contains them, oblige the others to yield and resign their situation; and hence a separation is effected. When oil and water, for instance, have been well shaken together, and afterwards the whole is left in a state of rest, the water, having more density than the oil, takes the lower position, and the oil rises to the surface. If this effect does not take place, it is owing to the intervention of one of the following causes: First, a kind of elective attraction, which may exist between the particles of different fluids, as when water and wine are mixed together, the water, though heavier than the wine, does not separate itself. Secondly, the viscosity of one of the substances, as when the whites of eggs are beaten together, and by that means a considerable quantity of air mixes with them; the air, though much lighter, has not power to disengage itself from the matter in which it is enveloped, in order to effect its escape.

If two fluids of different densities are placed in a state of equipoise with each other, and have the same base, their perpendicular heights above the horizon will be in a reciprocal ratio to their densities or specific gravities.

If, for example, mercury is put into an inverted siphon, and water is poured into one of the branches, in order to elevate the mercury in the other branch one inch above its level, it is necessary that the water should be about thirteen inches and an half high. The height of the water then will be thirteen times and a half that of the mercury; because the specific gravity of mercury is about thirteen times and a half as great as that of water.

This observation will also apply to the reciprocal action of air and water, or air and mercury upon each other. Many of the phenomena of hydrostatics and hydraulics are to be referred to the pressure of the atmosphere, for which we must refer to **PNEUMATICS**.

It is, however, proper on the present occasion, to call the reader's attention to some of the properties of this fluid, and he will easily remember, that as a fluid, air is possessed of gravity, and consequently presses upon all bodies which oppose it; and it is necessary to add, that like water, it presses in all directions. If, therefore, a small hole is made with a gimlet, either in the side or bottom of a cask or vessel which is quite full of liquor, it will not run out, because the external air which presses against the hole, sustains the liquor, which has not a sufficient height to overcome its pressure. Hence the necessity of a vent peg, to enable liquor to be drawn out of a full cask. The elasticity of the small quantity of air which is introduced at the vent presses the fluid, and overcomes the pressure of the air at the cock. There is an instrument in common use, called a valencia, for extracting small quantities of liquor out of the bung-holes of casks. It is a tube with a small aperture at the bottom and the top. When full, if the hole at the top is stopped with the thumb or finger, so as to prevent the pressure of the air at the top, the liquor will not run out of the hole at the bottom, being kept in by the force of the external air.

It is proper to observe, that all the effects which depend upon the pressure of air, take place in a room where the column of air is terminated by the ceiling, as well as without doors where the column of air has the whole height of the atmosphere; and the reason is, because the air in the room has a communication with that on the outside, supposing it to be only by means of the key-hole. Thus a barometer placed in a hall, will have its mercury as high as if it was placed in an open field.

The curious effects produced by siphons, all depend upon the pressure of the air.

A siphon is a bent tube, *ABC*, (fig. 3) made of glass, metal, &c. One branch of which *AB*, is shorter than the other *BC*. In order to make use of this instrument, place the extremity of the short branch in the vessel *A*, which may be supposed to contain any fluid matter, as water for instance. If the air then is drawn out of the siphon (fig. 4), by means of the long branch *x*, the liquor will begin to flow, and will not cease while the short branch *AB* remains immersed in the fluid. It is easy to see that the pressure of the air upon the surface of the fluid in the vessel, is the cause of its discharge through the siphon. For suppose *GF* the confines of the atmosphere, all the points of the surface *A* of the liquor will be equally pressed by the column of air *AF*; if, therefore, at some point of this surface, the pressure is suspended, the liquor must flow at that point, because it finds less resistance there than in any other part; this is therefore the obvious reason why the siphon becomes full immediately after the air is drawn out at the extremity *C*.

If the two branches of the siphon were of equal lengths, as *BA*, *BD*, the flow through the bent tube would not take place; because the column of air *DG* which would resist in *D*, being of an equal height with that which presses at *A*, would also be in equilibrium with it, in the same manner as the two columns of the fluid *BA*, *BD*. But since *BC*, one of the legs, is longer than the other, though the column of the air *GC*, which an-

swers to it, is really longer than that which presses in *A*; yet it is not capable of preventing the passage of the fluid. To understand this more perfectly, let us consider the column of air *GC* to be divided into two parts, one of which *GD*, would form an equipoise with the column of air *FA*, and would be capable of stopping the flow from the tube if the branch *BC* ended in *D*. The portion of fluid which fills the part *DC* of the siphon, will find no other resistance in *C* than one column of air *DC* of the same length with it, which is evidently very inferior to it in weight. This portion of fluid then flows out, because it greatly exceeds in weight the column of air which is opposed to it. But while it continues to flow, nothing sustains that which is above it, which flows necessarily, while the pressure of the air at *A* furnishes a new supply of fluid to replace that which runs out. It is by these means, that the water in the siphon continues to flow without intermission; because the resistance of the air in *C* is as much exceeded, as the length of the branch *BC* of the siphon exceeds that of the branch *AB*. In order to prove this, suppose there is added at *C* a tube to lengthen that branch, then it will plainly appear that in a given time more water will flow than would have been discharged without that augmentation to the branch *BC*.

Since it is the pressure of the air which elevates the fluid in the short branch *BA*, it follows, that the height of this branch is limited to thirty-two feet when the fluid is water, because the pressure of the atmosphere cannot elevate water higher; but when the liquor is mercury, the height of the short branch should not exceed thirty inches, because the atmosphere cannot sustain mercury at a greater height.

A siphon may be disguised in a cup, fig. 5, from which no liquor will flow, until it be raised above the bend of the siphon; but when the efflux once begins, it will continue to flow till the vessel be emptied. This has been called *Tantalus's cup*, because it is usual to place a hollow figure over the inner tube of such a length, that when the fluid has got nearly up to the lips of the figure, the siphon may begin to act, and empty the cup.

Intermitting springs, which puzzled philosophers formerly, are found to be natural siphons, which may be thus explained: Let *A* fig. 6, be part of a hill, within which there is a cavity *BB*, and from this cavity a vein, or channel running in the direction *BCD*. The rain that falls upon the side of the hill will sink and strain through the small pores and crevices in the hill, and fill the cavity *BB* with water. When the water rises to the level of *C*, the vein *BCD* will be full, and the water will run through it as a siphon, and will empty the cavity *BB*. It must then stop, and when the cavity is again filled, it will begin to run again.

III. The action of fluids on solid bodies immersed in them, has been treated of in **SPECIFIC GRAVITY**, which see.

To finish the subject of hydrostatics, however, we may add that it is evident that when a solid body is plunged into a fluid, it occupies a space in that fluid exactly equal to its own magnitude. The quantity of fluid then so displaced, either equals in density, and consequently in weight, the solid which displaced it; or, on the contrary, one of the two must

weigh more than the other. In the last case, which is most common, the quantity by which the heavier body surpasses the lighter, is called the specific weight or gravity.

If a body is heavier than the fluid in which it is immersed, it is evident that it will sink to the bottom by its specific gravity. If a body is lighter than the same bulk of the fluid into which it is plunged, a part of it will swim, and the remaining part which is immersed displaces a quantity of fluid which weighs exactly as much as the whole of the solid body.

The instrument used for finding the specific gravities of bodies, is called the hydrostatic balance (fig. 18.) See SPECIFIC GRAVITY.

It differs very little from a common balance that is nicely made; only it has a hook at the bottom of one of the scales, on which different substances that are to be examined may be hung by horse-hairs, or silk threads, so as to be immersed in a vessel of water, without wetting the scale.

If a body thus suspended under the scale, at one end of the balance, be first counterpoised in air by weights in the opposite scale, and then immersed in water, the equilibrium will be immediately destroyed; then, if as much weight be put into the scale from which the body hangs, as will restore the equilibrium, without altering the weights in the opposite scale; that weight which restores the equilibrium, will be equal to the weight of a quantity of water as large as the immersed body; and if the weight of the body in air be divided by what it loses in water, the quotient will shew how much that body is heavier than its bulk of water. Thus, if a guinea suspended in air, be counterbalanced by 129 grains in the opposite scale of the balance, and then, upon its being immersed in water, it becomes so much lighter as to require $7\frac{1}{4}$ grains put into the scale over it, to restore the equilibrium, it shews that a quantity of water of equal bulk with the guinea, weighs $7\frac{1}{4}$ grains, or 7.25; by which divide 129 (the weight of the guinea in air), and the quotient will be 17.793; which shews that the guinea is 17.793 times as heavy as its bulk of water. And thus, any piece of gold may be tried, by weighing it first in air, and then in water; and if upon dividing the weight in air by the loss in water, the quotient comes out to be 17.793, the gold is good; if the quotient be 18, or between 18 and 19, the gold is very fine; but if it be less than 17, the gold is too much alloyed with other metal.

By this method, the specific gravities of all bodies that will sink in water, may be found; first weighing the body in air, then in water, and dividing the weight in air by the loss in water.

But as to those which are lighter than water, as most sorts of wood are, the following method must be taken: A sort of pincers, or tongs, must be provided, to retain the substance to be examined under water. First weigh the body in air; then having balanced the tongs in water, fix to it the body to be weighed, which being lighter than water, will raise the tongs, and cause the other scale to preponderate. Observe the loss of weight of the body in water, and proceed as before.

There are some things that cannot be weighed in this manner, as quicksilver, frag-

ments of diamonds, &c. which must be put into a glass bucket hanging to the scale.

HYDROSULPHURETS, in chemistry. Sulphureted, or sulphurated hydrogen gas possesses the properties of an acid. It is absorbed by water, in considerable quantities, and the solution reddens vegetable blues; it combines also with alkalies and earths, and with several metallic oxides. The combinations which sulphureted hydrogen forms with bases have been called hydrosulphurets.

Sulphureted hydrogen combines with alkalies and earths, and forms with them compounds which may be distinguished by the following properties:

1. They are all soluble in water, and the solution is colourless.

2. When the solution is exposed to the air, it becomes green or greenish yellow, and deposits sulphur on the sides of the vessel in the state of a fine black crust.

3. After long exposure to the air, the solution becomes limpid and colourless; and on examination is found to contain only the sulphat of the base of the original hydrosulphuret.

4. The solution of the hydrosulphurets precipitate all metallic solutions; iron and lead, black; antimony, orange; arsenic, yellow.

The hydrosulphurets may be formed by dissolving or mixing the bases respectively with water, and causing sulphureted hydrogen gas to pass through them till they refuse to absorb any more. The excess of the gas is driven off by heating the solution. It is proper to cause the sulphureted hydrogen gas to pass through a small vessel of water before it reaches the base with which it is to combine, in order to separate any impurities with which it might be mixed. By this method solutions of the different hydrosulphurets in water may be obtained.

If these compounds be decomposed while they are colourless, by pouring upon them sulphuric acid, muriatic acid, or any other acid which does not act upon hydrogen, the sulphureted hydrogen gas exhales without the deposition of a single particle of sulphur; but if the hydrosulphuret has become yellow, some sulphur is always deposited during its decomposition, and the quantity of sulphur is proportioned to the deepness of the colour.

The yellow colour, therefore, which hydrosulphurets acquire by exposure to the atmosphere is owing to a commencement of decomposition. Part of the hydrogen of the sulphureted hydrogen abandons the sulphur, combines with the oxygen of the atmosphere, and forms water. By degrees, however, a portion of the sulphur is also converted into an acid; and when the proportion of sulphureted hydrogen is diminished, and that of the sulphur increased to a certain point, the sulphur and the hydrogen combine equally with oxygen.

If sulphuric or muriatic acids be poured upon a hydrosulphuret after it has been for some time exposed to the air, a quantity of sulphureted hydrogen gas exhales, sulphur is deposited, and after an interval of time sulphureous acid is disengaged. It is therefore sulphurous, and not sulphuric acid, which is formed while the hydrosulphuret spontaneously absorbs oxygen. This acid, however, is not perceptible till after a certain interval of time, when separated from the hydrosulphuret by means of another acid; because as long

as it meets with sulphureted hydrogen a reciprocal decomposition takes place. The oxygen of the acid combines with the hydrogen of the gas, and the sulphur of both is precipitated.

The affinities of the alkalies and earths for sulphureted hydrogen appear from the experiments of Berthollet to be as follows:

| | |
|----------|-----------|
| Barytes, | Ammonia, |
| Potass, | Magnesia, |
| Soda, | Zirconia. |
| Lime, | |

HYGROMETER, a machine, or instrument whereby to measure the degrees of dryness, or moisture of the atmosphere.

There are divers sorts of hygrometers; for whatever body either swells or shrinks, by dryness or moisture, is capable of being formed into an hygrometer. Such are woods of most kinds, particularly ash, deal, poplar, &c. Such also is catgut, the beard of a wild oat, &c. Stretch an hempen cord or lute-string, as A B, (plate Hydrostatics, fig. 21.), along a wall, bringing it over a pulley, B; and to the other end D, fix a weight E; into which fit an index F. On the same wall fit a plate of metal H I, divided into any number of equal parts, and the hygrometer is complete. For it is known from experience that moisture sensibly shortens the length of cords or fiddle-strings; and that as the moisture evaporates, they return to their former length. The weight, therefore, in the present case, upon an increase of the moisture of the air, will ascend; and upon a diminution of the same, it will descend.

Hence, as the index F will shew the spaces of ascent and descent; and those spaces are equal to the increments and decrements of the length of cord, or gut, A B D; the instrument will discover whether the air is more or less humid now, than it was at another given time.

But if a more sensible and accurate hygrometer is required, strain a whipcord or fiddlestring over several pulleys, C, D, E, F, and G, fig. 22, and proceed as in the former example. Nor does it matter whether the several parts of the cord are parallel to the horizon, as expressed in the figure or perpendicular to the same.

The advantage of this above the former hygrometer, is, that we have a greater length of cord in the same compass; and consequently greater contraction or dilatation.

The following is much more lasting: Take a nice balance and place in it a sponge, or other body, which easily imbibes moisture; and let it be in equilibrio, with a weight hung at the other end of the beam. Now if the air become moist, the sponge becoming heavier, will preponderate; if dry, the sponge will be raised up. This balance may be contrived two ways; by either having the pin in the middle of the beam, with a slender tongue a foot and a half long, pointing to the divisions on an arched plate fitted to it; or, the other extremity of the beam may be made so long as to describe a large arch on a board placed for the purpose, as is represented in the figure.

To prepare the sponge, it may be necessary to wash it in water; and when dry again, in water or vinegar, in which sal ammoniac, or salt of tartar, has been dissolved, and let it dry again, then it is fit to be used.

A, fig. 23, represents a thin piece of sponge, so cut as to contain as large a superficies as possible. This hangs by a fine thread of silk, upon the beam B, and is exactly balanced from another thread of silk at D, strung with the smallest lead shot, at equal distances, and so adjusted as to cause the index to point at G, in the middle of the graduated arch F G H, when the air is in a middle state between the greatest moisture and the greatest dryness. I, shews a little table or shelf for that part of the silk and shot which is not suspended to rest upon.

Both Dr. Hales and Dr. Desaguliers contrived another form of sponge hygrometer, on this principle. They made an horizontal axis, having a small part of its length cylindrical, and the remainder tapering conically with a spiral thread cut in it, after the manner of the fuzee of a watch. See fig. 24. The sponge is suspended by a fine silk thread to the cylindrical part of the axis upon which it winds. This is balanced by a small weight W, suspended also by a thread, which winds upon the spiral fuzee. Then when the sponge grows heavier, in moist weather, it descends and turns the axis, and so draws up the weight; which coming to a thicker part of the axis it becomes a balance to the sponge, and its motion is shewn by an attached scale: and vice versa when the air becomes drier. Salt of tartar, or any other salt, or pot-ashes, may be put into the scale of a balance, and used instead of the sponge.

HYMEN. See ANATOMY.

HYMENÆA, the bastard locust tree; a genus of the monogynia order, in the decandria class of plants; and in the natural method ranking under the 33d order, lomentaceæ. The calyx is quinquepartite; there are five petals, nearly equal; the style is in-torted; the legumen full of mealy pulp. There is but one species, the courbaril, which is a large tree growing naturally in the Spanish West Indies. The trunk is covered with a light ash-coloured bark, is often more than sixty feet high, and three in diameter. The seeds are covered with a light brown sugary substance, which the Indians scrape off and eat with great avidity, and which is very agreeable. At the principal roots under ground, is found collected in large lumps a yellowish red transparent gum, which dissolved in rectified spirit of wine affords a most excellent varnish, and is the gum anime of the shops.

HYMENOPTERA, derived from *ὑμην* membrane and *πτερον* wing, in the Linnaean system of natural history, is an order of insects having four membranaceous wings, and the tails of the females are furnished with stings, which in some are used for instilling poison, and in others for merely piercing the bark and leaves of trees, and the bodies of other animals, in which they deposit their eggs.

HYOBANCHE, a genus of the angiospermia order, in the didynamia class of plants. The calyx is heptaphyllous; the corolla ringent, with no under lip. The capsule bilocular, and polyspermous. There is one species a parasitical plant of the Cape.

HYOIDES. See ANATOMY.

HYOSCYAMUS, henbane, in botany, a genus of the monogynia order, in the pentandria class of plants; and in the natural method ranking under the 28th order, luridæ.

The corolla is funnel-shaped and obtuse; the stamina inclining to one side; the capsule covered and bilocular. There are eight species, one of which, viz. the niger, or common henbane, is a native of Britain. It grows on road-sides, and among rubbish. It is a biennial plant, with long fleshy roots which strike deep into the ground, sending out several large soft leaves, deeply flushed on their edges: the following spring the stalks come up, which are about two feet high, with yellow flowers standing on one side in a double row, sitting close to the stalks alternately. The seeds, leaves, and roots of this plant, as well as of all other species of this genus, are poisonous: and many well-attested instances of their bad effects are recorded; madness, convulsions, and death, being the common consequence. In a smaller dose they occasion giddiness and stupor. It is said that the leaves scattered about a house will drive away mice. The juice of the plant evaporated to an extract is prescribed in some cases as a narcotic; in which respect undoubtedly it may be a powerful medicine if properly managed. The dose is from half a scruple to half a dram. The roots are used for anodyne necklaces. Goats are not fond of the plant; horses, cows, sheep, and swine refuse it.

HYOSERIS, a genus of the polygamia aequalis order, in the syngenesia class of plants; and in the natural method ranking under the 49th order, compositæ. The receptacle is naked, the calyx nearly equal; the pappus hairy, or scarce perceptible. There are ten species, resembling dandelion.

HYOTHYROIDES. See ANATOMY.

HYPALLAGE, among grammarians, a species of hyperbaton, consisting in a mutual permutation of one case for another. Thus, Virgil says, "dare classibus auctos," for "dare classes auctis;" and again, "necdum illis labra admovi," for "necdum illa labris admovi."

HYPECOM, wild cummin; a genus of the digynia order, in the tetrandria class of plants; and in the natural method ranking under the 24th order, corydæles. The calyx is diphyllous; the petals four; the exterior two larger and trifid; the fruit a pod. There are three species, all of them low herbaceous plants with yellow flowers. The juice of these plants is of a yellow colour, resembling that of celandine, and is affirmed by some eminent physicians to be as narcotic as opium. From the nectarium of the blossom the bees collect great quantities of honey.

HYPERBATON, in grammar, a figurative construction inverting the natural and proper order of words and sentences. The several species of the hyperbaton are the anastrophe, the hysteron-proteron, the hypallage, synchysis, tmesis, parenthesis, and the hyperbaton, strictly so called.

HYPERBATON, strictly so called, is a long retention of the verb, which completes the sentence, as in the following example from Virgil:

*Interea reges: ingenti mole Latinus
Quadrifido vehitur curru, cui tempora circum*

*Aurati bis sex radii fulgentia cingunt
Solis avi specimen: bigis it Turnus in albis,
Bina manu lato crispans hastilia ferro:
Hinc pater Æneas Romanæ stirpis origo,
Sidereo flagrans clypeo & coelestibus armis;*

*Et juxta Ascanius magnæ spes altera Romæ
Procedunt castris.*

HYPERBOLA, in geometry, the section of a cone made by a plane, so that the axis of the section inclines to the opposite leg of the cone, which in the parabola is parallel to it, and in the ellipsis intersects it. The axis of the hyperbolic section will meet also with the opposite side of the cone, when produced above the vertex. See CONIC SECTIONS.

HYPERBOLE, in rhetoric, a figure, whereby the truth and reality of things are excessively either enlarged or diminished.

HYPERBOLIC CYLINDROID, is a solid figure, whose generation is given by Sir Christopher Wren, in the Philosophical Transactions. Thus, two opposite hyperbolas being joined by the transverse axis, and through the centre a right line being drawn at right angles to that axis; and about that, as an axis, the hyperbolas being supposed to revolve; by such revolution, a body will be generated, which is called the hyperbolic cylindroid, whose bases, and all sections parallel to them, will be circles. In a subsequent transaction, the same author applies it to grinding of hyperbolic glasses; affirming, that they must be formed this way, or not at all. Hyperbolic leg of a curve, is that which approaches infinitely near to some asymptote. Sir Isaac Newton reduces all curves, both of the first and higher kinds, into those with hyperbolic legs, and those with parabolic ones.

HYPERBOLIC line is used by some authors for what we call the hyperbola itself. In this sense, the plane surface, terminated by the curve line, is called the hyperbola, or hyperbolic space; and the curve line that terminates it the hyperbolic line.

HYPERBOLOIDES, are hyperbolas of the higher kind, the nature of which is expressed by

this equation: $ay^m \times x^n = bx^m (a + x^n)$: especially if $m > 1$, or $n > 1$, e. g. $ay^3 = bx^2 (a + x)$.

HYPERICUM, St. John's wort; a genus of the polyndria order, in the polydelphia class of plants; and in the natural method ranking under the 20th order, rotaceæ. The calyx is quinquepartite; the petals five; the filaments many, and coalited at the base into five pencils; the seed-vessel is a pencil. Of this genus there are 57 species, most of them hardy deciduous shrubs. The most remarkable are, 1. The hircinum, or stinking St. John's wort. Of this there are three varieties; one with strong stalks, six or eight feet high, broad leaves and large flowers; the other with strong stalks, broad leaves, and without any disagreeable odour; the third has variegated leaves. All these varieties are shrubby, and flower in June and July in such numerous clusters, that the shrubs appear covered with them; and produce abundance of seed in autumn. 2. The canariensis has shrubby stalks, and at the ends of the branches, clusters of yellow flowers appearing in June and July. 3. The ascyron, or dwarf American St. John's wort, has spreading roots, sending up numerous slender square stalks, a foot long, and at the end of the stalks large yellow flowers. 4. The androsamum, commonly called tutsan, or park-leaves, has clusters of small yellow flowers appearing in July and August, and succeeded by roundish berry-like black capsules. This grows naturally

in many parts of Britain. 5. The balearicum, or water-leaved St. John's wort, is a native of Majorca, and has a shrubby stalk, with reddish scarified branches, small oval leaves warted underneath, and large yellow flowers appearing great part of the year. 6. The monogynum, or one-styled China hypericum, has a shrubby purplish stalk, about two feet high, and clusters of small yellow flowers, with coloured cups, and only one style, flowering the greatest part of the year.

The tutsan long held a place in the medicinal catalogues; but its uses are very little thought of at present. The leaves given in substance are said to destroy worms. By distillation they yield an essential oil. The flowers tinge spirits and oils of a fine purple colour. Cows, goats, and sheep eat the plant; horses and swine refuse it. The dried plant boiled in water with alum dyes yarn of a yellow colour; and the Swedes give a fine purple tinge to their spirits with the flowers.

HYPHYDRA, a genus of the class and order monoecia gynandria; the male cal. is one-leaved; cor. none; stam. six. The female no cal. or cor.; caps. one-celled. There is one species, a little aquatic plant of Guiana, of no note.

HYPNUM, feather-moss; a genus of the natural order of musci, belonging to the cryptogamia class of plants. The anthera is operculated, or covered with a lid; the calyptra smooth; the filament lateral, and rising out of a perichætium, or tuft of leaflets different from the other leaves of the plant. There are fifty species, many of them natives of Great Britain; none of them, however, have any remarkable property, except the proliferum and parietinum. The first is of a very singular structure, one shoot growing out from the centre of another; the veil is yellow and shining; the lid with a kind of long bill; the leaves not shining; sometimes of a yellowish, and sometimes of a deep green. This moss covers the surface of the earth in the thickest shades, through which the sun never shines, and where no other plant can grow. The second has shoots nearly flat and winged, undivided for a considerable length, and the leaves shining; but the old shoots do not branch into new ones as in the preceding species. It grows in woods and shady places; and, as well as the former, is used for filling up the chinks in wooden houses.

HYPOCAUSTUM, among the Greeks and Romans, a subterraneous place, wherein was a furnace, to heat the baths.

HYPOCHÆRIS, hawk's-eye; a genus of the polygamia æqualis order, in the syngenesia class of plants; and in the natural method ranking under the 49th order, compositæ. The receptacle is paleaceous; the calyx a little imbricated; the pappus glumy. There are five species; none of which have any remarkable property, except the maculata, or spotted hawk's-eye. It is a native of Britain, and grows on high grounds. The leaves are boiled and eaten like cabbage. Horses are fond of this plant when green, but not when dry. Cows, goats, and swine eat it; sheep are not fond of it.

HYPOCHONDRIA. See **ANATOMY** and **MEDICINE**.

HYPOTHENUSE, in geometry, the longest side of a right-angled triangle; or it is that side which subtends the right angle.

Euclid, lib. 1. proposition XLVII. demon-

strates, that, in every rectilinear right-angled triangle, the square of the hypotenuse is equal to the squares of both the other sides.

This celebrated problem was discovered by Pythagoras, who is said to have sacrificed a hecatomb to the Muses, in gratitude for the discovery.

HYPOXIS, a genus of the monogynia order, in the hexandria class of plants; and in the natural method ranking under the 10th order, coronariæ. The corolla is divided into six parts, and persisting, superior; the capsule narrowing at the base; the calyx a bivalved glume. There are fourteen species, bulbs of America and the Cape.

HYRAX. Hyrax, a genus of quadrupeds of the glires order. The generic character is, front teeth in the upper jaw two, broad, somewhat distant; in the lower jaw four, broad, flat, twice crenated; grinders large, four on each side in both jaws; fore-feet with four toes; hind-feet with three toes; tail none; clavicles none. This genus is distinguished from all the rest of the glires by the remarkable circumstance of having four teeth in the lower jaw instead of two: these lower teeth are also of a different structure from the upper, being broad, short, and crenated or denticulated at the top: the upper teeth in this genus are also less sharp or pointed than in the rest of the glires. In other particulars the genus hyrax seems most nearly allied to that of cavia. The most remarkable species are:

1. Hyrax Capensis is a native of mountainous situations about the Cape of Good Hope; residing in the hollows of rocks, and leaping with great agility about the prominences of the irregular regions it frequents, though its general or walking pace is not remarkably quick. Its size is nearly that of a rabbit, and in colour it much resembles that animal, but is whitish beneath. It is said to be known at the Cape by the name of rock badger, but Mr. Allamand observes, that this is an improper name, since the structure of its feet evidently shews that it has no power of digging or burrowing. It is a diurnal animal, and by night retires into the cavities of rocks, &c.

This animal appears to be easily tamed, and in that state is observed to be remarkably cleanly, and of a lively and active disposition; leaping almost as readily and with as much security as a cat.

2. Hyrax Syriacus, or Syrian hyrax, seems to have been first clearly described by Mr. Bruce, in the appendix to his celebrated Abyssinian Travels. It is found in Ethiopia, in the caverns of the rocks, or under the great stones in the Mountain of the Sun, behind the queen's palace at Koscam. It is also frequent in the deep caverns in the rock in many other parts of Abyssinia. It does not burrow or make holes, as the rat and rabbit.

In the place of holes, it seems to delight in less close, or more airy places, in the mouths of caves, or clefts in the rock. They do not stand upright upon their feet, but seem to steal along as in fear, their belly being nearly close to the ground, advancing a few steps at a time, and then pausing. They have something very mild, feeble, and timid, in their deportment; are gentle and easily tamed, though, when roughly handled at the first, they bite very severely. The hyrax is supposed to

be the animal erroneously called by our translators of the bible cuniculus, the rabbit or coney. See Plate Nat. Hist. fig. 230.

3. Hyrax Hudsonius. Its colour is a cinereous brown, with the ends of the hairs white. It is a native of Hudson's Bay. Its size is nearly that of a common marmot; the feet are tetradactylous; of a similar form to those of the cape hyrax, but have rounded claws on all the toes.

HYSSOPUS, hyssop, a genus of the gymnospermia order, in the didynamia class of plants; the cor. has the lower lip with a small crenate segment; stam. straight, distant. There are three species; but only one of them, viz. the officinalis, or common hyssop, is cultivated for use. Besides possessing the general virtues of aromatics, they have been supposed useful in humoral asthmas, coughs, and other disorders of the lungs; and are said to promote expectoration.

HYSTERICUS. See **MEDICINE**.

HYSTRIX. Porcupine, a genus of quadrupeds, of the order glires. The generic character is front-teeth two, both in the upper and under jaw, obliquely cut; grinders eight; body covered with spines intermixed with hairs; four toes on the fore-feet; five on the hind.

1. Common porcupine. From their obvious external characters alone, without reference to the form and disposition of the teeth, the porcupine and the hedgehog might be placed together; but such is the dissimilarity of these organs, that the one must of necessity belong to the Linnæan order feræ, and the other to that of glires.

The singular appearance of the porcupine, so different from that of the generality of quadrupeds, must in the earliest ages have attracted the attention even of the most incurious; the variegated spines or quills with which it is covered, naturally suggesting the idea of a fierce and formidable animal: it is, however, of a harmless nature, and the quills are merely defensive weapons, which, when disturbed or attacked, the animal erects, and thus endeavours to repel his adversary.

The general length of the porcupine is about two feet from head to tail, and that of the tail about four inches. The upper parts of the animal are covered with long, hard, and sharp quills; those towards the middle and hind part of the body being longer than the rest, and measuring from nine or ten to twelve or fifteen inches in length: they are very sharp-pointed, and are variegated with several alternate black and white rings: the root, or point of attachment, is small: the head, belly, and legs, are covered with strong dusky bristles, intermixed with softer hairs: on the top of the head the hairs are very long, and curved backwards in the manner of a ruff or crest: the ears are short and rounded: the nose blunt; the upper lip divided by a strongly-marked furrow; the two fore-teeth, both above and below, extremely large and strong: the fore feet have four toes; the hind feet five; all armed with strong crooked claws: the tail is covered with short and rather flattish quills, which are often abrupt or truncated, rather than pointed at the extremities. This animal is a native of Africa, India, and the Indian islands: it is also found in some of the warmer parts of Europe, and is said to be not very uncommon in Italy and

Sicily; but is supposed to have been originally imported into those parts of Europe from other regions.

The power of darting its quills with great violence, and to a considerable distance, so confidently ascribed to the porcupine, has been doubted; but it is surely not improbable that the porcupine possessing, like other quadrupeds, the power of corrugating or shaking the general skin of its body, may sometimes by this motion cast off a few of its loose quills to some distance, and thus slightly wound any animal that may happen to stand in its way; and this may have given rise to the popular idea of its darting them at pleasure against its enemies. That it really does cast them off occasionally with some degree of violence there is no reason to doubt. The strongest and shortest of the quills are most easily detached, and are those which the animals dart against the hunters, by shaking their skin as dogs do when they come out of the water.

The porcupine feeds principally on roots, fruits, barks, and other vegetable substances: it inhabits holes or subterraneous retreats, which it is said to form into several compartments or divisions, leaving only a single hole or entrance. It sleeps much by day, and makes its excursions for food during the night. The female produces two young at a birth, and these, if taken early, are said to be easily tamed.

The porcupine admits of considerable variety as to the length and proportion of the quills in different specimens and from different countries: the long crested bristles on the back of the head, in particular, are much more conspicuous in some than in others. See Plate, Nat. Hist. fig. 231.

2. *Hystrix prehensilis*, is an American species, and is found in many of the hotter parts of that continent; particularly in Brasil, where it inhabits woods, and climbs trees; clinging occasionally to the branches by its tail, in the manner of some of the opossums and monkeys. It is said to feed not only on fruits of various kinds, but also on birds. It

sleeps during the greater part of the day, concealing itself in the hollows of trees, or beneath their roots. Its voice, according to Marcgrave, resembles the grunting of a pig. Its general length is about a foot, and the tail about eighteen inches. The whole animal, except on the belly and insides of the limbs, is covered with short, strong, and very sharp spines, of which the longest measure three inches, and are white, barred towards the points with black. The colour of the hair with which the under parts are covered is a dusky brown. The head is small; the nose extremely blunt; and the teeth very large and strong: the ears short, moderately large, and rounded; the feet have four toes each, with strong claws, and a tubercle in place of a fifth toe; the tail is covered with spines for about a third part of its length; the remainder being nearly naked, and strongly prehensile.

3. *Hystrix Mexicana*. The Mexican porcupine, which is placed as a variety of the *hystrix prehensilis* in the Gmelinian edition of the *Systema Naturæ*, seems to be justly considered by Mr. Pennant as a distinct species. It is as large, according to Hernandez, as a middle-sized dog, and is of a dusky brown colour, with very long bristles intermixed with the fur. This animal inhabits the hilly parts of Mexico, residing in woods, and feeding, like the former, on fruits, &c. It is said to be easily tamed.

4. *Hystrix macroura*. The iridescent porcupine is an animal of a very extraordinary appearance. It is of a very thick form, and is coated with short, stiff, needle-like bristles, or small spines, which, according to the different directions of the light, exhibit changeable colours, appearing either of a gilded green, or of a reddish tinge. If we except the gilded, or cape mole, it seems to be almost the only quadruped yet known with changeable-coloured hair.

5. *Hystrix fasciculata* is a native of Malacca. It differs from the common porcupine in several particulars, and especially in the form and length of its tail, which is naked, scaly, about a third of the length of the body,

and terminated by a tuft of long flat hairs, or rather small white laminae, resembling strips of parchment. The body measures fifteen or sixteen inches, and is consequently less than that of the European porcupine.

This species, like others of its genus (which nature seems to have provided with defensive weapons only), possesses a kind of instinctive fierceness: when approached, it stamps with its feet, and appears to inflate itself, raising and shaking its quills. It sleeps much by day, and is active only by night. It eats in a sitting posture, holding apples and other fruits between its paws, peeling them with its teeth.

6. *Hystrix dorsata* is a native of the northern parts of America, and is not uncommon in Canada. It is a short thick-bodied animal, approaching somewhat to the form of a beaver, and is remarkable for the length and fullness of its fur, which is soft, of a dusky brown colour, and intermixed with longer and coarser hairs with whitish tips. Edwards compares the size to that of a fox, though the shape is widely different. The spines are nearly hid in the fur, and are only visible on a close inspection: they are situated on the head and upper parts, as well as on the tail: the longest are those on the back, which measure about three inches, while those on the other parts are proportionally shorter: they are strong and sharp-pointed, and so formed as to appear, when examined with a magnifier, as if barbed at the tips with numerous, small, reversed points or prickles, and are so slightly attached to the skin as to be loosened with great ease: and the animal will sometimes purposely brush against the legs of those who disturb it, leaving several of the spines sticking in the skin.

It is said to feed principally on the bark of the juniper tree. It drinks by lapping, in the manner of a dog. It resides in holes under the roots of trees, on which, like some others of this genus, it often climbs, and is thus killed by the American Indians, who consider it as a useful article of food: they also use the quills by way of fringes, and for the purpose of ornamenting their boxes, &c.

INDEX TO THE TREATISES

IN THE FIRST VOLUME.

* * The letters *a*, *b*, *c*, refer to the columns—*a* to the first column; *b* to the second column; *c* to the third column.

AIR.

Air, different kinds of: See the particular names.
 Alkaline air, its composition, &c. 32 *b*.
 Atmospheric air, formerly accounted an elementary principle, 28 *c*. A permanently elastic fluid, 29 *a*. Component parts of, 32 *b*.
 Azotic air, or nitrogen gas, its definition and qualities, 31 *b*.
 Carbonated hydrogen gas, light and heavy, properties of, 33 *a*.
 Carbonic acid gas, (called also choke-damp,) its discovery 32 *c*. Properties of, *ib*. Its base more abundant in nature than that of any other gas, *ib*.
 Fixed air, origin of the term, 29 *b*. Fatal to animal and vegetable life, 29 *c*.
 Fluoric acid gas, its radical unknown, 35 *b*. Properties of, *ib*.
 Gas, origin of the term, and first theory of the composition of gas, 29 *a*.
 Gases, name for permanently elastic fluids, 29 *a*. Principal, noticed in modern philosophy, 30 *a*. For the different kinds of, see the particular names.
 Inflammable air, or nitrogen gas, (called also fire-damp,) its properties, &c. 31 *c*.
 Muriatic acid gas, its component parts, properties, &c. 34 *c*.
 Nitrous gas, composition and properties of, 33 *c*.
 Nitrous oxide, composition and properties of, 34 *a*. Fatal to animal life, &c. 34 *b*.
 Oxygenated muriatic gas, its definition and properties, 35 *a*.
 Phosphorated hydrogen gas, composition and properties of, 33 *b*.
 Sulphurated hydrogen gas, its properties, &c. 33 *b*. May be employed to imitate some mineral waters, *ib*. and also in a kind of sympathetic writing, *ib*.
 Sulphureous acid gas, no where found in a natural state, 34 *c*. Properties of, *ib*.
 Vital air, or oxygen gas, its discovery, 29 *c*. Definition and qualities of, 30 *a*. Its basis combined with a great variety of substances, 30 *b*. Different processes by which it may be obtained, 30 *b*, *c*. Reasons why it is the most essential of all the fluids to the support of life, 31 *a*. Pernicious, however, to animals who breathe it alone for a considerable time, 31 *b*.

ALGEBRA.

Addition, cases of, and rules, 49 *b*.
 Algebra defined, its origin, appellations, divisions, &c. 48 *b*. Signs used in, explained, 49 *a*.
 Quantities and properties of, *ib*.
 Division, cases of, and rules, 50 *a*, *b*, *c*.
 Equations, of, 51 *c*. Of the origin and composition of equations, &c. 57 *a*.
 Fractions, definitions of, 51 *a*. Problems in, *ib*. Addition, subtraction, division, and multiplication of, 51 *b*.
 Involution of quantities, 52 *a*.
 Multiplication, cases of, and rules, 49 *c*.
 Proportion, of, 54 *a*.
 Subtraction, general rule for, 49 *c*.

ANATOMY.

Abdominal viscera described, 84 *c*.
 Absorbent system, account of 85 *a*.
 Anatomy, definition of, 76 *c*. Divisions of, 77 *a*.
 Angiology, definition and account of, 185 *a*.
 Aorta, description of, 91 *a*. Branches from the descending aorta described, 93 *a*; from the termination of the aorta, 94 *b*.

Arterial system, account of, 91 *a*. For the different arteries, see their particular names.
 Bones, of the head, description of, 77 *b*. Trunk, *ib*. Extremities, 78 *a*. Cranium, 77 *b*. Face, 77 *c*. Teeth, *ib*. Spine, *ib*. Pelvis, 78 *a*. Thorax, *ib*. Arm and fore-arm, *ib*. Hand, *ib*. Thigh, 78 *b*. Leg, *ib*. Foot, *ib*. See Osteogony and Osteology: also the names of the different parts of the body.
 Brachial or humeral artery, its distribution, 92 *c*.
 Brain, description and structure of, 97 *c*. See Cerebrum, &c.
 Bursalogy, definition of, 78 *b*.
 Carotid artery, common, its distribution, 91 *b*.
 Cerebellum, description, &c. of, 99 *b*.
 Cerebrum, description, &c. of, 98 *a*.
 Chondrology, definition, &c. of, 77 *a*, 78 *b*.
 Ear, description and structure of, 96 *c*.
 Eye, description and structure of, 96 *a*.
 Femoral arteries, common, distribution of, 95 *a*.
 Fluids of the human body enumerated, 76 *c*.
 Heart, description of, 84 *b*, 87 *b*. Its situation and general conformation, 87 *b*. Its ventricles, 87 *c*. Its valves, 88 *b*. Its uses, 89 *b*.
 Iliac arteries, common, distribution of, 94 *b*.
 Lacteals, discovery and account of, 85 *a*.
 Lungs, description of, 84 *b*, 98 *b*. Their situation, general figure, &c. 89 *b*, to 90 *c*.
 Lymphatic vessels, discovery and account of, 85 *a*, to 86 *b*.
 Mediastinum, description of, 86 *c*.
 Medulla oblongata, description of, 99 *b*.
 spinalis, description of, 99 *c*.
 Mouth, and organ of taste, description and structure of, 97 *b*.
 Muscles, of the teguments of the cranium, description of, 78 *b*. Ear, 78 *c*. Eye-lids, *ib*. Eyeball, 79 *a*. Nose, *ib*. Mouth and lips, *ib*. Lower jaw, 79 *b*. Those about the anterior part of the neck, *ib*. Those between the lower jaw and os hyoides, 79 *c*. Those between the os hyoides and the trunk, *ib*. Those between the lower jaw and the os hyoides laterally, 80 *a*. Those about the entry to the fauces, *ib*. Those on the posterior part of the pharynx, *ib*. Those about the glottis, 80 *b*. Those in the fore part of the abdomen, *ib*. Those about the male organs of generation, 80 *c*. Those within the pelvis, 81 *a*. Those within the cavity of the abdomen, *ib*. Those on the fore part of the thorax, *ib*. Those between the ribs, 81 *b*. Those on the fore part of the neck, *ib*. Those on the back of the trunk, *ib*. Those on the shoulder, 82 *b*. Those on the arm and fore arm, *ib*. Those on the hand, 83 *a*. Those on the upper part of the thigh, 83 *b*. Those on the leg, 83 *c*. Those on the foot, 84 *a*. See Myology: also the names of the different parts of the body.
 Myology, definition and account of, 77 *a*, 78 *b*.
 Nerves See Neurology.
 Neurology, definition and account of, 77 *a*, 99 *c*. Of the nerves in general, 99 *c*. Of particular nerves, 100 *c*, to 105 *b*.
 Nose, description and structure of, 196 *c*.
 Osteogony, definition and account of, 77 *a*.
 Osteology, definition and account of, 77 *a*.
 Pelvis viscera described, 84 *c*.
 Pericardium, description of, 84 *b*, 87 *a*.
 Pleura, description of, 84 *b*, 86 *c*.
 Skin, and organ of touch, description and structure of, 97 *c*.
 Solids of the human body enumerated, 76 *c*.
 Splanchnology, definition and account of, 84 *b*.

Subclavian artery, distribution of the branches of, 92 *a*.
 Syndesmology, definition and account of, 77 *a*, 78 *b*.
 Thoracic viscera described, 84 *b*.
 Thorax, account of, and of its contents, 86 *b*.
 Veins, description and divisions of, 95 *c*.
 Viscera. See Abdominal, Pelvic, and Thoracic.

ARCHITECTURE.

Architecture, origin of, 135 *b*. Orders of, *ib*. Modern or practical, 139 *c*.
 Cathedrals, ancient, grand effect of their structure, 139 *b*, *c*.
 Domes, or cupolas, origin of, 139 *c*.
 Gothic, account of its origin and structure, 139 *a*.
 Houses, difference between those of Paris and London, 135 *b*. Structure of those of the ancients, 138 *a*. Considerations and directions in building houses, 139 *c*, to 142 *a*.
 Villas, Roman, structure of, 138 *b*. Description of that of Pliny, *ib*.
 Temples of the ancients, seven orders of, 137 *b*.

ARITHMETIC.

Addition, definition of, 147 *b*. Compound addition, 147 *c*.
 Arithmetic, origin of, 146 *c*. Marks used as abbreviations in, 147 *a*.
 Decimal fractions, account of, 151 *b*.
 Division, definit. and rule, 148 *c*. Compound, 149 *a*.
 Multiplication, definition and rule, 148 *a*. Compound, 148 *b*.
 Numeration, account of, 147 *b*.
 Practice, definition and general rule, 150 *a*.
 Proportion, compound, 149 *c*.
 Reduction, definition and rules, 149 *a*.
 Roots, of the extracting of, 152 *a*. Square root, *ib*. Cube root, 152 *b*.
 Rule of Three Direct, 149 *b*. Inverse, &c. 149 *c*.
 Vulgar fractions, account of, 150 *a*. Addition and subtraction of, 150 *c*. Multiplication and division of, 151 *a*.

ASTRONOMY.

Asteroids, account of, 172 *c*.
 Astronomy, definition and history of, 165 *b*.
 Celestial phenomena, account of, 166 *a*.
 Circles, three great in the heavens, 166 *c*.
 Comets, phenomena of, 177 *c* to 178 *b*.
 Constellations, lists of, 178, 179.
 Copernican system, account of, 166 *a*.
 Earth, opinions of the ancients respecting, 165 *b*, *c*.
 Eclipses, phenomena of, 175 *b* to 176 *b*.
 Elongation of the planets, account of, 169 *b*.
 Fixed stars, account of, 178 *c*.
 Matter, quantity of, in the sun and planets, 173 *b*, *c*.
 Planets, account of their nature, orbits, &c. 167 *b* to 168 *c*.
 Ptolemaic system, account of, 165 *c*.
 Satellites, phenomena of, 173 *c* to 175 *a*.
 Seasons, phenomena of, 171 *b*.
 Solar system, account of, 167 *b*.
 Sun, its diurnal and annual motions, 166 *b*, *c*.
 Tides, phenomena and doctrine of, 176 *b* to 177 *c*.
 Time, the equation of, 170 *b*, *c*.
 Tyconic system, account of, 166 *a*.
 Universe, grand system of, 179 *b*.

BLEACHING.

Bleaching, its antiquity, progress, &c. 225 *b*.
 Books. See Prints.
 Cotton, process of bleaching, 228 *b*.
 Flax and hemp, process of bleaching, 225 *b* to 228 *b*.
 Hemp. See Flax.
 Oxygenated muriatic acid, its great utility in bleaching, 226 *b*.

Prints and printed books, bleaching of, 229 *b*.
Potass, the first menstruum to be used in bleaching, 226 *a*.
Rupp, Mr. his apparatus for bleach. cloth, 227 *a*.
Silks, process of bleaching, 229 *b*.
Steam, process of bleaching by, 228 *a, b*.
Wool, process of bleaching, 228 *c*.

BOTANY.

Botany, definitions and systems of, 249 *b*.
Calyx, varieties of, 253 *b*.
Classes of plants, 252 *a*.
Corolla, varieties and parts of, 254 *a*.
Fructification, parts of, 250 *a*.
Genera of plants, 253 *a*.
Glossary of terms, 257 *a*.
Habits of plants, account of, 251 *b*.
Hybernaculum, account of, 251 *c*.
Inflorescence, account of the modes of, 250 *a* to 251 *b*.
Leaves of plants, divisions of, 249 *b*.
Linnean system, 249 *b* to end of article.
Natural classes or orders of plants, 256 *a*.
Orders of plants, 252 *c*. Table of, 253.
Parts of plants, 249 *b*.
Pericarpium of plants, varieties of, 254 *a*. 255 *a*.
Pistillum of plants, parts of, 254 *c*.
Props of plants, account of, 249 *c*.
Receptaculum, varieties of, 255 *c*.
Roots of plants, divisions of, 249 *b*.
Seeds, account of the parts of, 255 *b*.
Sleep of plants, different ways of, 251 *c*.
Species of plants, 255 *c*.
Stamina, account of the parts of, 254 *b*.
Trunk of plants, divisions of, 249 *b, c*.
Varieties of plants, 256 *a*.

CHEMISTRY.

Acids, account of, 333 *b*. Different kinds of, enumerated and described, 339 *a* to 342 *a*.
Animal substances, account of, 347 *b*.
Azote, or nitrogen, account of, 335 *b*.
Caloric, account of, 334 *c*.
Carbon, account of, 336 *a*.
Chemistry, definition and branches of, 329 *b*.
History of, 329 *c*.
Crystallization, method of, 333 *a*.
Decantation, methods of, 332 *a*.
Distillation, methods of, 332 *a*.
Earths, account of, 337 *b*.
Evaporation, methods of, 332 *a*.
Fermentation, vinous, 345 *c*. Acetous, 347 *a*.
Putrid, 347 *b*.
Filtration, methods of, 331 *c*.
Furnaces, constructions of, 333 *b, c*.
Fusion, methods of, 333 *a*.
Glossary of terms, 351 *a*.
Hydrogen, account of, 335 *c*.
Instruments, chemical, 331 *a*, 332 *b, c*.
Light, account of, 334 *a*.
Lixivation, method of, 332 *a*.
Metals, account of, 342 *a*. Different kinds of, enumerated and described, 342 *c* to 345 *c*.
Nitrogen. See Azote.
Operations, chemical, 331 *c*.
Oxygen, account of, 334 *b*.
Philosopher's stone, fiction of the, among the alchemists, 329 *c*, 330 *a*.
Phosphorus, account of, 336 *a*.
Precipitation, method of, 333 *a*.
Pulverization, methods of, 331 *c*.
Putrefaction, account of, 347 *c*.
Simple substances, account of, 333 *c*.
Solution, methods of, 333 *a*.
Sulphur, account of, 336 *b*.
Tables, of compound oxidable and acidifiable bases, 347 *c*. Of numerous combinations, 348 to 351 *c*.
Vegetable substances, account of, 346 *a*.
Universal remedy, fiction of a, among the alchemists, 330 *a*.
Washing, methods of, 331 *c*.
Water, doctrine of the composition of, 330 *c* to 331 *c*.

COMPARATIVE ANATOMY.

Anatomy of the various kinds of animals, 411 *b* to 413 *c*.
Circulation, respiration, and voice, differences in the organs of, 410 *b*.
Classification of animals, founded on the whole of their organization, 411 *a*.
Comparative anatomy, definition of, 409 *c*.
Digestion and assimilation, varieties in the organs of, 410 *b*.
Form, external, indicative of the sentient organization, 415 *c*.
Generative organs, varieties in, 410 *c*.
Motions, animal, organs subservient to, 414 *a* to 415 *c*.
Muscles, forms and actions of, 414 *c*.
Secretion, varieties in the organs of, 411 *a*.
Skeleton, general view of, 414 *a*.
Sense and motion, differences in the organs of, 410 *a*.
Table of subdivisions of the classes of animals, 412 *b* to 413 *a*.

CONIC SECTIONS.

Cone, description of, 420 *a*. Its properties, 421 *a*.
Conic sections, methods of investigating their properties, 421 *b*. Their general properties, 423 *a*. Their uses, 423 *b*.
Equations of conic sections, 422 *c*.

DIAL AND DIALLING.

Card, to make a dial on a, 511 *b*.
Dial, easy method for constructing, 510 *b*.
Dialling, philosophical principles of, 513 *a*.
Dials, different sorts of, 508 *b*. Principles of their construction, 508 *c*.
Globe, terrestrial, dialling by, 509 *a*.
Table of the sun's place and declination for every day, 512.

DRAWING.

Altitude, and action of the muscles, instructions respecting, 557 *a*.
Beasts, birds, fishes, instructions for drawing, 556 *a*.
Directions, particular, for the student, 560 *b*.
Drapery, directions for drawing, 558 *b*.
Faces, instructions for drawing, 560 *c*.
Flowers, fruits, herbs, trees, &c. instructions for drawing, 555 *c*.
Human figure, instructions for drawing, 556 *a*.
Landscapes, directions for drawing, 558 *c*.
Lights and shades, distribution of, 559 *c*.
Mechanical drawing, instructions for, 55 *c*.
Mixed figures, directions for drawing, 561 *b*.
Outline, instructions respecting the correctness of, 559 *b*.
Passions, expression of, 558 *b*.
Transparencies, 562 *a, b*.

DYEING.

Black, dyeing of, 574 *b*.
Blue, dyeing of, 573 *a*.
Brown, dyeing of, 574 *c*.
Compound colours, dyeing of, 575 *a*.
Dyeing, principles of, 571 *b*.
Mordants, definition and list of, 572.
Red, dyeing of, 574 *a*.
Yellow, dyeing of, 573 *b*.

ELECTRICITY.

Animal electricity, account of, 608 *c*.
Attraction, electrical, experiments demonstrating, 603 *b, c*.
Aurora borealis, electrical nature of, 607 *b*.
Battery, electric, account of, 601 *b, c*.
Conductors attached to the electrical machine, account of, 600 *b*.
metallic, origin of, 596 *b*. 606 *b*.
Discoveries relative to electricity, history of, 595.
Electric matter, nature of, 596 *a*.
Electrics and conductors, lists of, 597 *c*.
Electrometers, account of, 602 *a* to 603 *a*.
Electrophorus, account of, 603 *a, b*.
Evaporation, of the electricity produced by, 608 *c*.

Fish, account of an unnamed one that possesses electrical properties, 610 *b*.
Franklin, Dr. his theory of electricity, 599 *b*.
Glass, first discovery of its electric power, 595 *a*.
Gymnotus electricus, account of, 609 *b*, to 610 *a*.
Heat and light, the matter of, analogous to that of electricity, 597 *a*.
Heating, or cooling, of the electricity produced by, 608 *b*.
Jars, for accumulating the electric fluid, account of, 600 *c*.
Instruments, or apparatus, electrical, 600 *a*.
Leyden phial, account of, 601 *a, b*.
Lightning, discovery of its identity with electricity, 596 *b*.
Machine, electrical, different inventions of, 598 *a, b*.
Melting, of the electricity produced by, 608 *a*.
Orrery, electrical, account of, 604 *a, b*.
Phenomena, electrical, 603 *b* to 605 *b*.
Positive and negative electricity, distinction of, first made by Dr. Franklin, 596 *b*.
Principles, general, of electricity, 596 *c*, 600 *a*.
Rain, hail, snow, and vapours, conjectures as to the electrical nature of, 607 *a, b*.
Siluris electricus, account of, 610 *a*.
Theory of electricity, 599 *a*. Dr. Franklin's, 599 *b, c*.
Thunder and lightning, meteors, water-spouts, &c. of the electrical nature of, 605 *b*. Safest situations during a thunder-storm, 607 *a*. Method of calculating the distance of a thunder-cloud, *ib*.
Torpedo, its electrical properties, 609 *a*.
Tourmalin, electrical properties of the, 603 *b*.
Water-spouts, electrical nature of, 605 *b*, 607 *c*, 608 *a*.

ENTOMOLOGY.

Abdomen of insects, description of, 635 *a*.
Antennæ of insects, description of; their use uncertain, 633 *c*, 634 *b, c*.
Classification of insects, 637.
Entomology, attentions necessary in the study of, 633 *c*.
External parts of the body of insects, 634 *a*.
Head of insects, description of, 634.
Hearing, question whether insects possess this sense, 634 *a*.
Insects deemed by some naturalists the most imperfect, and by others the most perfect of animals, 633 *b, c*.
Limbs of insects, description of, 635 *a* to 636 *a*.
Metamorphoses of insects, account of, 636 *c*.
Sexes of insects, 636.
Smell, question whether insects possess this sense, 634 *b*.
Trunk of insects, description of, 635 *a*.

FARRIERY.

Anatomical description, and skeleton of the horse, 705 *b, c*.
Diseases to which horses are subject, 702 *a* to 703 *a*.
Origin and present state of the veterinary art, 699 to 701.
Phlebotomy, or blood-letting, 704 *b*.
Shoeing of the horse, 703 *b*.
Teeth and eye of the horse, 703 *b*.

FLUXIONS.

Direct method of fluxions, 755 *a*.
Doctrine of fluxions, 754 *b*.
Inverse method of fluxions, 755 *b*.
Notation of fluxions, 754 *c*.

FORTIFICATION.

Definition and origin of fortification, 764 *c*.
Field fortification, 767 *a*.
Irregular fortification, 766 *b* to 767 *a*.
Regular fortification, 765 *a* to 766 *b*.

GARDENING.

Cultivation of a garden, 818 *b* to 819 *b*.
Flower-garden, directions respecting, 817 *a*.
General remarks on gardening, 813 *c*.
Landscape or picturesque gardening, observations on, 817 *b* to 818 *b*.

Management of a garden, 819 *b*.
Mixed garden, consisting of vegetables, fruits, and flowers, directions for forming a, 814 *a* to 817 *a*.
Propagation of plants, directions respecting, 819 *c* to 821 *b*.

GEOGRAPHY.

Circles described by the sun in the heavens, enumerated, 834 *a* to 835 *a*.
Climates, origin and use of that term, 835 *c*.
Grand divisions of the earth specified, 836 *c*.
History of geography, 831 *c* to 833 *a*.
Principles of the science of geography, 833 *a, b, c*.
Zones, account of the, 836 *a*.

GEOMETRY.

Algebra, application of, to geometry, 843 *b*.
Definition and origin of this art, 839 *c*.
Explanation of terms used in geometry, 840 *a* to 842 *b*.
Problems in geometry, 842 *b* to 844 *b*.
Usefulness of geometry, 844 *b*.

GUNNERY

Artillery, when first brought into use, 835 *a*.
Gunpowder, its explosive force, 835 *a*.
Origin of the art of gunnery, 834 *c*.
Velocity which bullets acquire from the force of gunpowder, 835 *b*. Description of a machine for measuring the velocity of bullets, 835 *c*.

HISTORY.

Ancient history, the best authors of, enumerated, 919 *b, c*.
Definition and uses of history, 918 *c*.
Duty of the historian, 920 *c*.
Helps for the study of history, 919 *a*.
Historians, English, the most eminent, pointed out, 919 *c* to 920 *b*. Of other countries, 920 *b, c*.

HUSBANDRY.

Board of agriculture, its origin, 932 *a*.
Flowing meadows, description of, 936 *c*. Management of, 937 *a, b*.

Grasses, natural and spontaneous, the different varieties of, specified, 941 *b* to 942 *a*.
Hay, directions relative to making, 942 *c* to 943 *b*. Stacking and thatching, *ib*.
Husbandry, rise and progress of, 931 *c*.
Irrigation, or watering land, 935 *c* to 936 *c*.
Manures, the properties, advantages, and application of the various kinds of, enumerated, 937 *b* to 941 *b*.
Meadow lands, management of, 942 *a, b*.
Pasture-lands, management of, 944 *c*.
Ploughing, directions for, 945 *a*. Implements used in, 945 *b*.
Soils, general remarks on, 932 *b* to 933 *a*. Clavey or argillaceous, 933 *b*. Loamy, 933 *c*. Chalky or calcareous, 934 *a*. Sandy or siliceous, 934 *b*. Gravelly, 934 *c*. Peaty or mossy, *ib*. Vegetable, 935 *b*. Improvement of soils, 935 *a*. Commixing of soils, 935 *c*.
Tillage-land, instructions respecting, 943 *c*. Obstructions to tillage, 944 *b*.

EXPLANATION OF THE ARTERIES, VEINS, AND ABSORBENTS, IN THE ANATOMICAL PLATES,
OMITTED TO BE INSERTED IN ITS PROPER PLACE.

FIG. I. ARTERIES.

1. Aorta
2. Trunk of the coronal artery
3. Ligamentum arteriosum
4. Subclavian artery
- 5-5. Carotid arteries
- 6-6. Vertebral arteries
- 7-7. Arteries of the lower part of the face, &c.
- 8-8. Temporal arteries
- 10-10. Trunks to the foramina-narium
- 11-11. Occipital arteries
- 12-12. Arteries to the fauces
- 13-13. Contorsions of the carotids
- 14-14. Carotid arteries
15. Contorsions of the vertebrae
16. Vertebrae on the medulla-oblongata
18. Arteries within the skull
19. Arteries of the larynx
- 20-20. Arteries to the muscles of the neck and scapula
- 21-21. Mammary arteries
22. Arteries to the muscles of the os-humeri
23. } Divisions of the arteries of the arm.
24. }
- 25-25. Branch of artery not always found
- 26-26. External artery of the cubitus
- 27-27. Arteries of the hand and fingers
29. Bronchial artery
30. Descending aorta
31. Intercostal arteries
32. Celiac artery
33. Hepatic arteries
34. Gall-bladder, on which the arteria-cystica ramifies
35. Lower coronary artery
36. Pyloric artery
37. Epiploic artery
38. Ramifications of the coronary artery
39. Upper coronary artery
- 40-40. Phrenic arteries
41. Splenic artery
43. Upper mesenteric artery
44. Superior branches of the mesenteric
45. Lower mesenteric artery
- 49-49. Emulgent arteries
50. Vertebral arteries of the loins
51. Spermatic arteries
52. Arteria Sacra
- 53-53. Iliac arteries

- 54-54. Iliacus externus
- 55-55. Iliacus internus
- 56-56. Umbilical arteries
- 57-57. Epigastric arteries
60. Arteries to the penis
61. Artery of the urinary bladder
62. Arteries of the pudendum
63. Penis
64. Glans-penis
65. Upper part of the dorsum-penis
66. Corpora cavernosa-penis
67. Arteries of the penis
68. Septum of the corpora-cavernosa
69. Crural artery
70. Arteries to the muscles of the thighs and tibiae
71. Part of the crural artery
72. Three trunks of the arteries of the leg
73. Arteries of the foot.
- A. Semilunar valves
- B. B. Small portions of the basis of the skull
- C. Pituitary gland
- D. D. Ophthalmic arteries
- E. E. Arteries of the cerebellum.

FIG. II. VEINS.

- a. a. Vena-cava
- b. Descending trunk of a cava
- c. Ascending trunk
- d. d. Subclavians
- e. Vena-azygos
- f. Intercostal veins
- g. Mammary veins
- i. i. Internal jugulars
- l. l. External jugulars
- m. Right axillary vein
- n. Cephalic
- o. Basilic
- q. Phrenic
- s. s. Emulgents
- w. Internal iliacs
1. Vena sacra
2. Spermatic veins
3. Epigastric
4. Saphena.

FIG. III. ABSORBENTS.

1. The neck
- 2-2. Jugular veins

3. Vena-cava. Superior
- 4-4. Subclavian veins
5. Beginning of aorta, pulled on one side to shew the thoracic duct
6. Branches
7. Carotid artery
9. Trachea
10. Spine
11. Vena azygos
12. Descending aorta
13. Celiac artery, dividing into 3 branches
14. Superior mesenteric artery
15. Right crus diaphragmatis
- 16-16. Two kidneys
17. Right emulgent artery
18. External iliac arteries
19. Internal iliac artery
20. Cavity of the pelvis
- 21-21. Spine of the os ilium
- 22-22. Groins
23. A lymphatic gland in the groin, receiving lymphatics from the lower extremity
- 24-24. Lymphatics of the lower extremities
25. A plexus of lymphatics on the side of the pelvis
- 26-29. Musculi psoæ
27. A plexus of lymphatics, which having passed over the brim of the pelvis at (25), and having entered the cavity of the pelvis, next ascends and passes behind the iliac artery to (29).
28. Lymphatics of the left side, passing over the upper part of the os sacrum, to meet those of the right side.
29. Right psoas, with a plexus of lymphatics on its side
31. Spaces occupied by lymphatic glands
32. Trunk of the lacteals
33. The same dividing into two branches
34. Thoracic duct
35. Duct passing under the crus diaphragmatis, and under the right emulgent artery
38. Thoracic duct, passing under the curvature of the aorta, to be inserted into the left subclavian vein
39. A plexus of lymphatics passing upon the trachea from the thyroid-gland to the thoracic duct.
